Wintering Seed Potatoes.—Amateurs are often troubled as to the proper storing of their seed Potatoes for the winter. The simplest plan is to get a number of bloater boxes, costing one penny each, and cut off 1 in. of each of the thin sides, leaving the stout ends as before. One of these will hold a peck of tubers, and if Kidneys, these should be stood on end, the sprout end upwards. A dozen of these boxes will thus hold about a sack of Potatoes, and that is a large quantity of seed for an amateur. When full these boxes may be placed one on the other, and it will then be seen that there is a free circulation of air passing between each lot of tubers. As long as that is the case tubers have plenty of light, and are kept dry; they will never make growth that cannot be kept sound and robust until planting time. Placed one on the other, twelve boxes would take up but a trivial amount of space in any cool room, and they might be moved now and then, putting the top ones to the bottom, and *vice versâ*.—A. D.

FRUIT.

A Few Good Pears.—The four Pears here illustrated are well worthy the attention of planters either on a large or small scale. They are good for large or small gardens, or for growing for profit or home consumption. Beurré Diel is of the first size and quality, and is ripe from October to December. On some soils it attains a large size, but if flavour be aimed at it is best to grow it on espaliers in the way we illustrated in Gardening a few weeks ago. The tree is a free grower and a good bearer. Van Mons Leon Leclerc is one of the finest Pears in cultivation. Grown as a pyramid, it yields large crops of the most exquisite flavoured fruits, which ripen from November to December. It is a grand market Pear. Doyenné du Comice is one of the most productive of Pears. In some cases the fruits exceed 1 lb. in weight. We have indeed at the present moment before us a photo of five Pears of this variety, which we are told weighed in the aggregate 4 lb. 3 oz. It is a well-tried kind, which can be well recommended for small gardens. It is fit for use during November and December. Duchesse d'Angoulême is one of the best market Pears grown. It does well on walls, espaliers, or as a standard, and bears large crops of fine-flavoured fruit, which bear carriage remarkably well, and always command a ready sale in the market. Beurré Clairgeau is a Pear of the first quality. The tree is a strong grower, but never requires much pruning. It generally bears a heavy crop of fruit, either on walls or when grown as a pyramid.

MANURING FRUIT TREES.

The importance of manuring cannot be overestimated by those who desire to have healthy trees and good sound fruit. After a tree has thoroughly matured its produce, it is much exhausted and requires nourishment; it is therefore in the best condition to benefit by a judicious application of well-rotted manure. When the juices are no longer absorbed by the fruit, they are directed towards the buds containing the embryo crop of the following year, and on the fact whether such buds are well fed or starved depend both the quality and quantity of the future fruit. Any one who is in the habit of observing the manner in which the same varieties of fruit are grown in various gardens cannot fail to have noticed a great diversity between those which are well grown and those badly grown, some being fine and abundant, others scanty and inferior. Now, it should be borne in mind that trees continue to derive nourishment and support from their roots during the whole winter; in fact, they are storing up vigour and strength to carry them through the trying period of blossoming and setting. This is especially the case with Peaches, Nectarines, Pears, Apples, &c. Unsuccessful setting and stoning, and consequent failure of the crop, are too frequently attributed to bad spring weather or late frosts. The real cause of these disasters must, however, be

sought for, for the most part, in weakness and want of vitality—the result of bad and injudicious feeding. Proper mulching in autumn or winter would have done much to supply these deficiencies. The manure should not be (as I have often seen it) heaped round the bole of the tree (perhaps for a considerable way up the stem), thus encouraging the growth of suckers from the original stock, and doing mischief instead of good, but a small portion of soil should be removed from the roots as far as they extend; the manure may then be applied, but not allowed to come in direct contact with them, and the soil should be raked back over the manure. By this process the roots are induced to come to the surface for their food, and become matured by the warmth of the summer sun. The manure should be good material, containing nourishment in a soluble state, whose beneficial substances can be washed down by rain or artificial watering. I repeat that the manure should be good. Too often it is rendered poor and useless by over fermentation. Manure is best rotted by means of slow and moderate fermentation. If the heat be too great, the ammonia is driven off and the manure becomes littery, dry, and inert, and consequently of little value; but when it is properly fermented, the ammonia remains absorbed, and is nutritious and highly beneficial. Trees derive very little good, if any, from unfermented manure. To heavily manure a tree every third or fourth year (the common practice) is not advisable; it should be done moderately every year. Nature herself points out to us the best season for this top-dressing. She spreads a thick litter of fallen leaves over the roots, thus giving nourishment in autumn and protection in winter, while in spring and summer a carpet of green grows up around the trees, thus preserving moisture and preventing evaporation. So should we in like manner in autumn and winter feed and protect and in spring and summer top-dress, to retain the dews and rain, and to prevent dryness. W. N.

Improving Weakly Fruit Trees.—Well-managed trees are always a redeeming feature, even when other matters in the garden furnish evidence of niggardliness or neglect. No doubt cold springs and other unfavourable climatal conditions exert at times a prejudicial influence, but well-managed trees, that have a sufficiency of healthy roots are never permanently crippled, however much they may be temporarily checked by unfavourable weather. Keep the roots in a healthy, growing condition, and the branches, if properly cared for, will soon recover their natural vigour, There is no better way of keeping trees in health than by putting new mould about their roots; and this is a good time to do such work. It often happens if a watchful eye be kept on the trees, and the first symptoms of failing health noted, that some new turfy mould placed about their roots brings them into healthy fruit-bearing condition, instead of going from bad to worse, until ultimately they have to be removed to the rubbish-heap. It is only another example of the truth of the old adage, "A stitch in time saves nine," and not only so, but it saves a good deal of heart-burning besides, as it lowers a man, not only in his own estimation, but also in the estimation of others, to have his trees in bad health from causes that ought to be under control. There are some places where new turfy mould is difficult to obtain, but something might be done—some effort made—at least to shift the responsibility of failure—if failure there must be. A very large number of fruit trees die annually, or are removed incurable, that might have been restored to health if new turfy mould had been placed round their roots in time. But the work should be done carefully, and, if possible, without unnecessary exposure. In carrying out the details of such work, one must be guided in some measure by the condition of the trees, the position which they occupy, and the quantity of new mould at command, but the more of the exhausted soil we can remove, supplying its place with fresh, the better will it be for the trees, and the longer will they live and bear good fruit. I need hardly mention that all bruised, broken, or unhealthy roots should be pruned away. —H. D.

Mixed Cropping in Orchards.—In this part of Kent an extensive area is devoted to orchards which are cropped on the mixed plan. In this way the rows of standard Apples and Pears are planted at double the ordinary distances apart, and rows of dwarf-spreading bush Apples or Pears are planted alternately; these again have rows of Kentish Cob nuts or Filberts planted between them, and Gooseberries or Currants in the intervening spaces. Under this system good crops of some of these fruits are ensured in all seasons, and as Gooseberries are mostly gathered green, the shade, while protecting them from frost, does not injuriously affect them. The Black Currant is also in great request for preserving purposes. The bush-trained Apples, Nuts, &c., are kept down quite low, and form open, wide-spreading heads. The centres of standard trees are well thinned out, but the outer young wood is left tolerably thick, forming a regular umbrella-shaped head, and the crops they bear amply testify to the suitability of the practice. Grafting and double grafting of approved market sorts are largely practised in this district, and on our strong, clayey loam, resting on ragstone foundation, the trees attain large proportions, their stems being more like those of forest trees than of ordinary fruit trees. Cherries thrive best in the lighter soils on the elevated portions of hillsides.—J. G., *Maidstone*.

Turquoise-berried Vine.

THE TURQUOISE-BERRIED VINE.

(VITIS HETEROPHYLLA HUMULIFOLIA.)

This has become near London a universal favourite as an ornamental climber or trailer, and indeed few ornamental Vines are more beautiful than it is in autumn. The annexed illustration represents both fruit and leaves about half their natural size, but unfortunately does not convey any idea of the delicate colour of its oblate fruits. It grows well in the shade at the end of a cold greenhouse, and it would probably fruit well out-of-doors, but our feathered friends would soon dispose of the berries. It is readily propagated by layering and by means of cuttings made of the ripe wood, as in the case of the Grape Vine. This Vine, we believe, was distributed a few years ago by Messrs. Veitch & Sons, of Chelsea, although it has for many years been known in English gardens.

TOWN GARDENING.

Pinks (Indian and Japanese.)—Hardly anything will be found to stand the smoke and dirt of towns so well as these. Though really perennials, and having the power of being perpetuated by cuttings, they are better raised from seed every year, as even as if they would stand the winter they always look very straggling and untidy the next year, but this trying season nearly always proves fatal to them. If you have a frame and want early blooms, sow the seed in boxes of loam, leaf-mould, and sand in March, and prick off and plant out as soon as large enough; a gentle heat will cause the seed to germinate more quickly and freely if early in the season, but they will do very well in a cold frame early in April. They may, however, be sown out-of-doors in April either in nursery beds or where they are wanted to flower, with almost as good results as by the more troublesome method. Of course they will not bloom quite so early in this case, but the difference will not be much. Do not buy, as a rule, cheap packets of seed, but go to a good shop and do not grudge 6d. or 1s. for it. The best double Indian Pinks should be obtained, and some of the finest flowers come from the Dianthus Heddewigi and diadematus classes. The Chinese or Japanese Pinks are single, and the new Eastern Queen and Crimson Belle, sent out by Messrs. Carter, are extremely beautiful. Indeed, in our opinion nothing can surpass these last for effect in bedding. They should be treated exactly in the same manner as the Indian Pinks; plant out 6 in. or 8 in. apart, as they will not grow quite so freely as in the country, and tie up the flower-stems to neat stakes. All should have a rich soil; good loam enriched with some well-rotted manure is about the best. Give them a sunny situation.

Pyrethrums.—There are now two distinct classes of this plant, both of which are almost equally suitable for the town garden. The first is the old Golden Feather, or Feverfew, grown only for its elegant yellow foliage, and now so largely used in bedding out. The other class is grown for its flowers, which are very bright in colour and showy. This grows to a height of 2 ft. or more, and is treated as a herbaceous perennial. There are many named varieties now to be purchased. The Golden Feather should always be treated as an annual. Sow the seed in light soil in March or earlier, in a little heat

if you can. Prick out 1½ in. apart in boxes, and grow on in cold frames or under glass. Plant out at the end of May from 4 in. to 8 in. apart; 6 in. is a good medium. It will grow in almost any soil that is light and rich; while young, boxes filled with spent hops in a decayed state suit it admirably. When in the beds, keep all blooms picked off as they show, for they are anything but pretty, and take the colour out of the leaves. The flowering Pyrethrums should be purchased in spring, as roots; the price is from 4s. to 6s. per dozen for good named kinds. A good selection of varied kinds would be Andromeda, lilac-rose; Aurora, creamy-white; Brilliant, rosy-purple; Candidum plenun, white; Delicatissimum, bright rosy-lilac; Emile Lemoine, purplish-crimson; Fulgens plenissimum, rich carmine; Le Dante, shining rose; Michael Buckner, rich rosy-crimson; Niveum plenum, pure white, very double; Roseum plenum, rosy blush; Solfaterre, sulphur, golden centre. These are very useful for cut flowers. Give them a deep, rich, well manured soil and plenty of water, and they are sure to do well. When the flowers are dead, cut down the stems and cover with a little litter to protect the plants from frost. In very bad situations it would perhaps be better to divide the plants in autumn, and keep them in a cold frame, otherwise do not disturb them till spring.

Snapdragons (Antirrhinums).—These should be sown early in spring and treated as annuals, as they do not stand the winter well. Sow in February or March in a gentle heat or sunny window, using light loamy soil. Prick off into boxes, and plant out in May. If sown any time in March, and kept growing, all will flower the same year, but the earlier they are started the better.

Stocks.

These sweet and beautiful flowers succeed so well in the town garden that they should be grown by everyone. Nothing seems to stand the dirt and smoke so well. There are many varieties, but for ordinary display the German or Ten-week will be found most useful. These are annuals, and bloom throughout the summer. The light soil usually found in town gardens suits Stocks admirably, as they do not like a damp, heavy, or close soil, and never attain any size in such. They are extremely fond of lime or mortar rubbish, crushed fine, but though the soil is light, it must be rich as well to suit them, so work in a quantity of well-decayed manure when preparing the beds and dig deeply.

Sowing.—The seed of the annual kinds should be sown as early as possible, as the longer time the plants have in which to grow before coming into flower the finer will be both plants and bloom. Do not forget this, as it is a most important point. Seed may be purchased in many different colours, and if sown and kept separately, one or more fine parti-coloured beds may be had; but in most cases a packet of mixed seed, costing 6d. or 1s., will suffice, and many dozens of plants may be raised from such a packet. The best soil for seed sowing is about equal parts of loam, leaf-mould, and sand, rather less of the latter, perhaps. The pot or box must have plenty of broken bricks or crocks for drainage, as if this point is not carefully attended to, the plants are very apt to go off just at the surface of the soil, especially in the early part of the season. On this place a thin layer of moss or spent hops, and then place the soil, sow the seed thinly; to this end wide boxes are better than pots. When sown early, a frame with a gentle heat of 60° is the best place for the seed-pan, but a greenhouse or sunny window will do, and by the end of March it will be safe to sow in a cold frame; but always sow early if you can. Keep the box close to the glass and in as much light as possible after the seedlings are well up, though, when young, they must be shaded from hot sun.

Transplanting.—When the young plants get the second pair of leaves, prick out into boxes in cold frames or protected beds in good rich soil (two parts loam, and one part each of leaf-soil and old rotten manure with some coarse sand is best now) about 2 in. or 3 in. apart. Here they may remain until it is time to plant them out. This should be carefully done; choose cloudy weather if you can, as they are very apt to flag badly in sunshine after replanting. Give them a thorou h soaking an hour or two before removing them, and take up singly with as much soil round the roots as you can get, and loosening or disturbing the same as little as possible. Plant 8 in. or 10 in. apart, pressing the soil firmly about the roots; give another good watering, and if the sun shines hot and strong within a few days afterward, they must be shaded. In planting discard all the extra tall and strong growers; these will generally be found to have long, coarse, and forked roots instead of a nice tuft of fibrous ones; such plants always turn out single flowers, whereas the aim of the gardener is to have only double ones. These are mostly rather small and compact growers, and such only should be planted. It is the practice of some to leave the plants growing in not much soil, and rather cramped at the roots in pots or shallow boxes until the flower-buds show, when they can easily be distinguished, the single ones having long pointed buds, with four equi-distant cracks or marks down the sides, and the double ones full, round, crumpled-looking buds. This is a very good plan, though the plants may suffer a little by being cramped and removed after the flower-buds show, a thing always to be avoided with nearly everything, but we have known very fine plants that were so treated; to avoid injury as far as possible, put the plants in their places as soon as ever the difference in the buds can be seen.

Situation.—The bed for Stocks should have an open and airy position, exposed to the full power of the sun. The plants should be plentifully watered in dry weather, especially when coming into bloom, and each should be supported by a neat stake to prevent its being blown about by winds. Treated thus, German Stocks are, in June and July, a sight not often seen.

Virginian Stocks.—Where there are no conveniences for early sowing under protection, the Virginian Stocks are useful; these are hardy annuals, and may be sown out-of-doors in March or April. But these are not nearly so fine as the German; in fact, not to be compared with them. Ten-week Stocks may be sown out-of-doors in protected nursery beds at the end of March, but, like the German, they are the better for a little care and early sowing.

The Intermediate Stock.—This is a great favourite, and produces larger heads of bloom than the German, and is biennial. The seed should be sown exactly the same as described above, but in August or September, and the plants should be pricked off and potted singly if possible, and kept through the winter in a cold frame, then planted out in spring. These should be put wider apart, as they are larger growers. If sown early in spring these will flower in the autumn. The Emperor and Queen Stocks are perennials; they are very fine, but a town winter generally kills them. The Brompton Stocks, too, are fine; they are biennials, like the Intermediate.

Sunflowers.—We cannot say that these are at all beautiful, but they are very effective, in a manner, and what is more, they will grow and do anywhere. They will, of course, grow and flower much finer in a deep and rich soil than in a poor one, for they are terribly greedy things, and can scarcely be overfed. Sow the seed out-of-doors in March or April, thin out, and transplant if needful. We used to have these and Marigolds come up all over the place by thousands in spring, self sown, and where they have once got a start, they will do the same; and these self-sown plants always do better than any others.

Verbenas are too well known to need comment. It is difficult, if not impossible, to keep these through the winter in a town, the only way being to get a few strong cuttings struck early, and potted off singly, and well established before winter. The shoots produced by these are taken off in spring and struck in heat. Old plants taken up from the borders inevitably die, and pots or boxes of young cuttings taken in September, as is usually done, generally perish also; so that you must either get a few strong young plants in 5-in. pots to keep through the cold weather and take cuttings from in the spring, or purchase afresh every year. If the former plan is followed, the cuttings should be growing when taken off, about 3 in. long, and March or the early part of April is the best time. Put them pretty thickly in light soil in pots or boxes (leaf-mould and sand rather rough is as good as anything for soil), and place in a gentle, sweet hotbed of about 70°. When rooted, admit air, and pot off singly when ready; or they may be planted 3 in. apart in cold frames or pits, with a glass or calico covering, and be left there to harden till planting out time. But, unless when distinct colours must be had, and if a little heat can be applied, we recommend the use of seedlings, as they are, when well grown, so much more vigorous in growth and flower than plants from cuttings. Get a packet of mixed hybridised seed from a good firm, and sow it as early as possible; if later than the middle of March, the plants will be behind the other bedding things. Sow thinly in well-drained boxes, using leaf-mould and sand in rather a rough state, not sifted, only lumps picked out, and left loose and rough on the top. Place in a good bottom heat of 70° or 75°, and keep close till the seeds have germinated; they must then be kept close to the light, not be over-watered, and have a fair supply of fresh air. As soon as the plants form the second pair of rough leaves, pinch out the points beyond, and when they shoot again prick off singly. It is better if they can still have a little heat, though they will do at this stage if pretty strong in a cold frame. Keep close for a few days and then admit plenty of air. Plant out where required in May. They would do rather better if potted separately when fit, and grown on till planting-time in small 3-in. pots. These plants are rather particular as to soil, and will not do well in a damp, cold, and heavy material. They delight in a free, rich, light soil, into which their long, delicate, and fibrous roots can easily penetrate, so that the best material they could have would be a light, sandy, and peaty loam, mixed with a good proportion of leaf-mould and some old manure. If you cannot get peaty loam, mix one-third or half of good sandy peat with it. The bed should be deep, at least 18 in., and well drained. But good Verbenas can be grown in any wholesome light soil if it is enriched with plenty of leaf soil or well rotted manure. From 1 ft. to 18 in. is quite close enough for strong plants, and when they begin to grow the shoots should be well pegged down with hairpins or hooked twigs regularly, so as to cover the beds with an even mass of foliage and flowers. Thus treated, we have had beds of Verbenas in which not an inch of soil was to be seen, all one carpet of rich green leaves, and the foliage in turn almost hidden with immense trusses of flowers; and any one can do the same. A great deal has been said and written about Verbenas in pots, but they are a great deal of bother, and do not grow half as well as in beds, at least that is our experience, and in a town especially we know they will not do any good in this way.

Zinnias.—These are now far superior to what they were some years ago. They are now really handsome flowers, especially the double ones, and the colours, though not brilliant, are glowing and intense. Sow in March or the first week in April in a good, rich, light soil, and place the box either in a cold frame or very gentle heat. Prick off singly and pot when fit, the main thing being never to let the plants receive a check in any way. Do not over-water, as they are liable to damp off at the collar. Plant out in May in deep rich soil, and when they grow, tie up to neat stakes. They must have a sunny situation. These have one great advantage over most other annuals, viz., that the flowers, instead of soon fading, continue in beauty for weeks without in the least deteriorating.—B. C. R.

Mildness of the Season.—In a garden near Esher Station, Surrey, December 11, was picked a bunch of Violets, Primroses, Polyanthus, and Cowslips, and the lowest the thermometer registered on the nights of December 9 and 10 was 42° and 45°, and on June 9 and 10 last, 40° and 45° showing it was colder in June than December.—F. H. S.

—— As an instance of the mildness of the present season, I might mention that I have during the past week picked flowers of Blue Nemophila from autumn-sown seed. Primroses and Violets are in bloom in many gardens about here.—W., *Christchurch.*

House and Window Gardening.

CYPRIPEDIUM INSIGNE AS A WINDOW PLANT.

Let it be known for the benefit of those immediately interested in the culture of plants in rooms that there is at least one of the interesting family of Orchids that may be easily and satisfactorily grown without the aid of a heated glass structure during the winter months. The species of Lady's Slipper here mentioned is as easy to grow as many of those soft-wooded subjects which form the chief delight of the small grower, and with ordinary care will last in good health in the same pot for years. The plant when doing well forms a mass of lance-shaped, leathery foliage, of a fresh bright green, and which may be as easily sponged and kept free from dust and other impurities as those of the India-rubber. It is therefore an easy matter to keep it clean and in good health, and I should add that washing the leaves, provided that the operation be carefully conducted, cannot be too frequently performed, as if the pores get clogged with dust, the foliage assumes a sickly hue, and the roots get into an inactive state.

During the winter season a warm dwelling-room suits it well, and if properly treated it will, at the beginning of the winter, just when flowers of any kind are most welcome, commence to throw up its curiously formed blooms, which, in the dry air of an apartment, last a long time in beauty. The roots are fleshy, and liable to decay when either too much water is given or drainage is not so free as it should be. At the same time the soil must be at all times maintained in a moist state, so that in the case of this plant waterings should be light and often enough to prevent the compost from quite drying out, and I need scarcely add that when the plant is making its growth in the summer much more water will be needed than when it is in a state of comparative rest, although I should observe that the resting process so often mentioned in connection with Orchid culture does not apply to the Lady's Slipper, which quickly loses its freshness and vitality if the soil is allowed to become and remain dry for any length of time.

From the end of May to the middle of October there is no better place for this plant than a cold frame or handlight in a north aspect, the comparatively cool and moist atmosphere being just what is favourable to a healthy development of crown and foliage. Where, however, such accommodation does not exist there need be no hesitation in retaining the plant in the dwelling all through the summer months, placing it in a light position, and frequently, in fact daily when the weather is hot and parching, sprinkling overhead with clean water. As before stated, a plant will last some years in the same pot without needing to be shifted, but should the grower find that his specimen has attained sufficient luxuriance to warrant its removal to a larger receptacle, let him take a pot one size larger, fill it half full of drainage, laying thereon some Sphagnum Moss, and re-pot in a compost of fibrous peat, mixing therewith a little Sphagnum and small pieces of crock. Keep the crowns well up above the level of the pot, and press the soil in firmly, but gently. J. Cornhill.

Byfleet.

TREES AND SHRUBS.

CRANBERRY CULTURE.

There is no fruit so acceptable during winter for tarts as Cranberries, yet how seldom do we see them grown, a circumstance which may arise from a mistaken notion that they are difficult to cultivate, or from an idea that building tanks in which to grow them is expensive. The finest Cranberry beds in the kingdom, perhaps, are at Ashburnham, in Sussex; yet their construction is most simple. They were formerly fish stews, originally about 12 ft. wide; some Oak stakes 3 in. square were driven into the ground 2 ft. from the side, and on these were nailed 1-in. Oak boards to the depth of 16 in. The bottoms of the beds were formed of brick-bats, in order to allow the water free access to the roots. The best soil for Cranberries is peat and leaf-mould with a good supply of sand; rough peat ought to be put over the bricks to keep the soil from getting amongst them. During the early stages of growth Cranberries require flooding, but more especially should this be done when they are coming into flower; the water should never be allowed to get below the side board. These beds were so arranged that the water from one pipe served the whole by allowing it to pass from one to the other, there being only a Grass walk of 6 ft. wide intervening. It is astonishing how long Cranberries will keep on bearing without any additional outlay. Some of these beds which I renewed had been fifty years under constant cropping, and Cranberries are very profitable, realising readily 5s. per gallon. Those who contemplate forming beds ought first to consider where a good supply of water can be had from; then, selecting a light airy position, but still not too exposed, have a bed of the required width excavated to the depth of 5 ft., and puddled with clay sufficiently to hold water; secure a waste pipe, say 3 in. below the top of the bed; when you require the water higher this may be easily done by placing some clay around the pipe to the required height. It is most essential not to allow the water to become stagnant. Do not plant too thickly, because for a few years they grow rapidly, and if crowded do not bear freely. The variety most suitable to grow is the American Cranberry (Oxycoccus macrocarpus) lately figured in Gardening. A. H.

Caterpillar of the Vapourer Moth

THE VAPOURER MOTH.

(ORGYIA ANTIQUA.)

The caterpillars of this common little moth are sometimes abundant, and they are then very destructive to various plants in gardens, shrubberies, and orchards. Though they do not confine their attentions to any particular kind of plant, they are especially fond of fruit trees, Limes, and Roses. There is not, unfortunately, much that can be done towards destroying this insect; the eggs are not sufficiently conspicuous to make it worth while to search

Vapourer Moth.

for them. The caterpillars are best destroyed by picking them off the plants they are feeding on, or spreading a large sheet or cloth under the trees or bushes and shaking or knocking the caterpillars into it, when they can be easily collected and killed by pouring boiling water over them. Search should also be made for the female moths, which differ very much from the males in general appearance and habits; having no wings, or only the smallest rudiments of them they are quite incapable of flight, and their movements being very sluggish, they are very easily caught when found; but as they are of a dull greyish-brown colour, it is not very easy to detect them. The males can be caught in a common butterfly net; they may frequently be found flitting about even in the brightest sunshine in search of the females. Of course the earlier in the season the moths can be caught the better, as it is very desirable that as many as possible should be destroyed before they have had opportunities of pairing; and if a few females can be killed before they have laid their eggs, the number of caterpillars will be much less. There are several broods of this insect during the summer and autumn. The eggs laid by the females of the last brood do not hatch until the following May, and the first brood of moths make their appearance in June; and from that time to the end of September or the beginning of October there are several broods. The moths are most common in August and September. The caterpillars are exceedingly curious and beautiful, being ornamented with tufts of hair, which vary very much in appearance on different parts of their bodies. When fully grown they spin round themselves a cocoon of silk mixed with hairs, within which they become chrysalides. The caterpillars, when fully grown, are about 1½ in. long; they vary very much in general colour from blackish to pale greyish-blue and white. Their bodies consist of twelve joints, of which the first three, the sixth, seventh, eighth, ninth, and last each have a pair of legs; on each joint are several tubercles, from each of which springs a tuft of long greyish hairs, in addition to which, on either side of the first joint, is a tuft of long hairs directed forwards; these hairs vary considerably in length, and are much thickened at the tips. The fifth joint is furnished with two similar tufts, one on either side; and the eleventh joint is provided with one of the same description on the centre of the back inclined backwards. The fourth and following three joints have on the back of each a thick short brush of hairs, which are all of the same length and generally white or yellowish in colour, but sometimes they are grey, reddish, or nearly black; between each of the brushes is a transverse black line on the back. S. S.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

December 27.—Pointing over herbaceous borders and the spaces among bush fruits; sowing Carrots and Radishes under glass; putting young Pelargoniums into their flowering pots; putting in Vine eyes in pit, and plunging them in fresh leaves; putting in another forcing of Strawberry plants, Mint, and Tarragon; washing Stephanotis and Camellias; syringing Azaleas for thrips, using 5 oz. of soft soap to a large potful of water; thinning plantations; beginning to prick over Asparagus land.

Dec. 28.—Digging shrubbery borders; sowing Radishes, Cauliflowers, and Lettuce, in orchard house; also sowing Syon House Cucumbers; potting a few old Calceolarias to make large plants for conservatory; extra-covering Celery; filling up bins in potting shed with manure, leaf-soil, and loam; putting a layer of ashes in cutting pit in which to plunge cutting pots; pruning bush fruits.

Dec. 29.—Putting in Fuchsia cuttings and plunging them in pit in heat; making edges ready for turf wherever the latter has got worn or died away; extra covering seed Potatoes; giving large tree Mignonette a layer of manure as a top-dressing; making a bed in a frame for Carrots, getting in cow manure for Roses.

Dec. 30.—Putting in a few Petunia cuttings and plunging them in bottom-heat; putting in cuttings of Crotons and plunging them in bottom-heat; putting in another batch of Asparagus and taking out first crop; hardening off first batch of Lilacs now in full flower.

Dec. 31.—Putting stock plants of scented Verbenas into heat for cutting; planting some young Gooseberry

trees; also a bed of Peppermint; shifting Pelargoniums, placing them in pits, keeping them cool and dry, and giving them plenty of air; putting Musk into heat, and Mignonette on the back shelf of a cold Vinery; looking round Hollies and Conifers, and dashing a little gas-tar against them to keeping off rabbits; cutting down autumn-struck Heliotropes, to induce them to break before potting them off; pruning pillar Roses.

January 1.—Digging land for Onions; sowing Parsley; also Sweet Peas by hedge side; shifting Nemophilas into 6-in. pots; cutting Alicante and Lady Downes Grapes for bottling; putting in cuttings of Justicias, Chrysanthemums, and Heliotropes; also some White Currant cuttings; putting Forget-me-nots in heat and keeping them at 50° at night; also Seakale, Asparagus, and Rhubarb; giving creepers in conservatory border a watering; tying up frame Lettuces as required.

Glasshouses.

Bedding Plants.—Dahlias, Gladioli, &c., should be stored in convenient places beyond the reach of frost; and this should also be carefully excluded from structures containing bedding plants, which should always, if well rooted, be kept as cool and quiet as possible, as it is by no means advisable to encourage growth in the absence of light and air. Nothing, however, is so injurious to bedding plants at the present season as damp; every possible care, therefore, must be taken to prevent drip from the roofs of such houses or pits which may contain them. All dead and decaying leaves, &c., must be removed whenever necessary, and every opportunity taken which the state of the weather may afford to admit fresh air, to render the plants as hardy as possible. During dry or frosty weather, get, as soon as possible, some manure prepared, ready to be applied to the flower beds and borders as soon as the spring-flowering plants and bulbs are removed. Any work that can be done that will forward operations in the spring or summer, when one does not know what to turn to first, should now be attended to. The exhibitor of florist flowers will have plenty to do in preparing his stands and boxes in which the stands or trays are conveyed to the exhibition; they may be painted and varnished, stowing them away when dry where they can be kept free from dust. Labels may be made and painted. Some persons like to write on dry paint, but wet paint is best, and the labels may be painted a second time before they are used. Sticks may also be prepared of various lengths and thicknesses; paint them green, and then dry them and tie them up in bundles ready for use. Pegs for layering Carnations and Picotees may also be cut out of any branches that may be most convenient. Beech and Hornbeam are amongst the best for this purpose. Failing these, wire, about the diameter of that used for ladies' hair-pins, answers well.

Fruit.

In this, the last calender of the year, it is but natural that notice should be made of those fruits that have in spite of bad weather been up to the usual average, both as regards quantity and quality, and though as a matter of course the remarks about to be made only apply locally, yet they may serve generally as some slight guide to the inexperienced who may be contemplating fruit tree planting. At least the trees named in the list will possess the merit of hardiness, and no kind is mentioned except those which have given a fair average crop, and which are of passable quality. They are as follows: Apricots—Musch Musch and Moorpark. Apples, dessert—Devonshire Quarrenden, King of the Pippins, Court of Wick, Cellini, Margil, Ribston Pippin, Court Pendu Plat, Cockle Pippin, and Lemon Pippin. Kitchen Apples—Lord Suffield, Hawthornden, Golden Noble, Blenheim, Lord Derby, Yorkshire Greening, Wadhurst Pippin, Kentish Fillbasket, Wellington, Warner's King, London Pippin, Winter Colmar, and Hambledon Deux Ans. Gooseberries—Red Warrington, Companion, Rough Red, Rumbullion, White Champagne, and Whitesmith. Nectarines—Pitmaston Orange and Downton. Peaches—Early Louise, Early Grosse Mignonne, Royal George, Bellegarde, Noblesse, and Barrington. Pears—Williams' Bon Chrétien, Beurré d'Amanlis, Flemish Beauty, Brown Beurré, St. Michel Archange, British Queen, Beurré Superfin, Beurré Hardy, Fondante d'Automne, Autumn Bergamot, Beurré de Capiaumont, Comte de Lamy, Seckel, Swan's Egg, Beurré Diel, Durandeau, and Pitmaston Duchess. Plums, dessert—Jefferson and Kirk's; kitchen—Early Orleans, Victoria, Pond's Seedling, and Autumn Compôte. In order to avoid such pressure of work in spring, let all manure aud soil wheeling be finished, stakes cut and pointed, labels made, and trees that require it relabelled. Nails can be eleaned, shreds cut, bunches of matting for tying, and small twigs for laying in the new shoots of wall trees—these, together with other jobs that will suggest themselves, may all now be done by way of forwarding operations when the busy time arrives. When the air is dry and free from frost open the fruit-room ventilators for an hour each day. All decayed fruit should be removed forthwith, and it may be worth while to wipe over the finer Pears with a dry cloth, in order to ensure their better preservation. Easter Beurré and Ne Plus Meuris, two kinds of Pears on which we depend for supplies in January and February, are sometimes so specky and subject to mould, that without thus drying they would fail to keep at all.

Bowl of Chinese Miniature Trees.

Raspberries should be planted; for this fruit the ground should be wel enriched by digging into it a good dressing of manure previous to planting; existing plantations of this fruit should be pruned and tied, and, where stakes are used, renewing such as are decayed; few crops require, or will better pay for a liberal use of manure than Raspberries. Even old plantations of them that have become weak can frequently be brought round by enriching the ground and otherwise bestowing on them judicious cultivation. One of the principal things to be observed in the case of the Raspberry is never to use a spade amongst them; the greater portion of the roots lie near the surface, and if the spade be employed in digging, quantities of them necessarily get injured; even fork culture should not be too deep.

Vegetables.

Endive and Lettuce.—Plants of these in frames and under hand-lights or bell-glasses should now be well attended to, giving them plenty of air when the weather is mild, but guarding against their getting wet, as they are less likely to suffer from severe frost, when the soil in which they are growing is dry on the surface, than they otherwise would be. When frozen, those in frames should have a mat thrown over the glass when the sun comes upon it, as the effects of being suddenly thawed are most disastrous. Hand-lights and bell-glasses ought to be similarly protected on the south side by means of litter or evergreen branches stuck in the soil, so as to screen the plants. Lettuces at the foot of south-walls may be protected by placing boards before them in a slanting position propped up, so as not to allow them to touch the plants. Endive covered with boards for blanching should, during frosty weather, be completely covered over with several inches of litter, for, if frozen, they will decay.

Celery.—Care should be taken that Celery is not subjected to much frost, or it will not keep so long, however firm and solid the variety may be; for covering material the common Brake is a good material where it is plentiful, or stable litter may be used; but whatever is employed will be found much more effectual if not in absolute contact with the tops of the Celery. To prevent this, take some stout pieces of old Pea sticks and push them down in the rows between the plants, then take some of the longest and straightest of the Pea sticks, or such as have been used for Runner Beans, and tie them lengthways to the upright sticks a few inches above the tops of the Celery; on these place the litter or other material, letting it hang well over the sides like thatch; this will be the best way of protecting it from frost, and costs little more in additional labour than simply placing the material upon the tops of the Celery.

Broccoli is frequently saved from being killed in severe frost by the slight protection afforded by laying old Pea sticks down moderately close upon them, as these break the full force of the cutting frosty wind. During severe frosts, or when there is an appearance of snow, cover Parsley with shutters or boards, if no frames are at hand, not allowing the covering material to absolutely touch it.

Chinese Miniature Forest Trees.—A correspondent asks how these wonderful little trees are produced by the Celestials, and as I have had some success in the process myself I will describe my lessons and experience in the art accurately from notes taken at the time. On Christmas Eve, 1870, a family gathering took place in the house of a friend of mine, who had travelled a good deal in China and Japan, and the conversation turning upon Genghee horticulture, my friend was describing a little Oak tree he had seen 59 years old and 3 in. in height. An incredulous smile from all present irritated my friend to such an extent that, summoning a Chinaman, or boy (you can never tell whether a Chinaman is 10 or 100), he explained at some length the subject of the conversation. The pagan child looked up with that bulbous vacuity of countenance which inspires implicit confidence, and remarked, "Allee light; Johnny sabe. Give Johnny one piece olange (Orange), lilly buck Acorn." He was supplied with an Orange and an Acorn from the hoard of one of the junior members of the family, and in stoic silence set to work. He cut a hole the size of a shilling in the Orange, and cleverly extracted all the pulp and juice. This empty skin he filled with some Cocoa-nut fibre, fine Moss, and charcoal, just stiffened with a little loam; into this he stuck the Acorn, in about the centre of the Orange peel. He repeated the process with another Orange and a Date stone, and remarked, "Settee olange topside windel," and the Oranges were put on the window-shelf in vases, and the heathen Chinee relapsed again into unconsciousness. For some weeks, when he thought no one was looking, he would creep into the room, and gently water the Oranges through the hole he had cut, and carefully sprinkle the surface that he could get at with wood ashes. At the end of about four weeks the trees appeared above the soil in both cases, and at the same time roots were pushed through the skin of the Orange. Johnny was delighted, and carefully razed the roots flush with the Orange skin (which curiously did not rot), and every week he would cut the roots off close to the peel. The plants became about 4 in. high, and then stopped, becoming gnarled and twisted like a veteran Oak and Palm. At the end of two years and a half the pagan was satisfied; he finally cut off the roots, which were now ¼ in. thick, and produced a most lovely effect, mottling the Orange peel, and having painted the ends of the roots black, he varnished the whole, and declared the growth finished. He was right; the trees never grew again, but until 1878 were quite healthy, and great curiosities. One morning Johnny returned to the land of the sun, and with him disappeared

the Orange "plantation." My friend started another pair, but without success, until, at my suggestion, he placed an Acorn and a Date stone into thumb pots in peat and loam. This was in July, 1879; every six weeks he turns the plants out of the pots, or rather I do it for him when in the way, and we pinch off the roots on the outside of the pots, and re-plant the trees. Though not such a success as the China boy's Oranges, they are nevertheless well matured little Oak trees, 5 in. high (the Date died last autumn), and I hope they will live for many years to come. A different plan I have pursued with considerable success is as follows: I obtained a wide-mouthed jar, and suspended from a card placed over the mouth an Acorn, so that it only *just* touched the water. It speedily grew and threw out roots, and whenever the roots got 3 in. long I shortened them all back. The tree became about 4 in. high and stopped, becoming quite matured and old. It was suspended from the mouth of the jar by copper wires, and the ends only of the roots were kept in water to a depth of about 1½ in. It subsequently died in the possession of a friend, who let the water touch the stem, and so killed it. I hope these directions may prove useful to any of your subscribers taking up this extraordinary form of horticulture.—Girofle.

GLASSHOUSES & FRAMES.

ARDISIA CRENULATA.

Those who have a warm house at command should not fail to grow this plant, as it is extremely useful at this time of the year for window, table, or conservatory decoration. It is best propagated by means of seed, which should be sown early in the year, so as to get a long season's growth. The latter end of January is a good time, but a temperature of 65°, with, if possible, a little bottom-heat, is necessary to get them up well. As soon as the young plants are large enough to handle, prick them out in a pan and tranfer them before they commence to crowd each other into small pots, using a nice, free, light compost, consisting of loam, leaf-mould, and peat in equal parts, adding to it a good dash of silver sand. The Ardisia revels in heat and moisture when growing, but does not attain to a sturdy development, unless exposed to the full influence of light. The best place for this plant is a shelf in a stove or warm house, where it not only gets the benefit of every ray of light, but where it at the same time enjoys on favourable occasions a tolerably free circulation of air. By the end of August, if the plants have been well attended to, they will have filled 2½-in. pots full of roots, and may then be kept somewhat cooler, and may be wintered if so desired in an intermediate house. The following year they may be shifted into 4½-in. pots and treated as before. By the end of the summer each plant will have formed a little standard crowned with dark green foliage, and loaded with bright red berries, and presenting an extremely neat, fresh, and cheerful appearance. The next year they may be shifted into 6-in. pots, but the most useful size is 4½-in.; therefore, a little seed should be sown every year. There is also a white-fruited variety, which demands the same treatment. J. Cornhill.

Byfleet.

Anemone Robinsoniana.—I know of nothing more exquisitely lovely than a fully-expanded patch of this beautiful flower on a bright spring morning. It is a rare British wild plant; I know of its occurrence in Norfolk and Essex, and I believe it has also been found in Kent and Sussex. It has long been cultivated in the Oxford Botanic Garden and in a few other choice collections, and may now be had at most of the hardy plant nurseries, but was practically unknown to the general public till a few years ago, when Mr. Robinson found it growing wild, and, struck with its marvellous beauty, so frequently spoke of its charms, that it became a general favourite.—H. C.

Pelargonium Comte de Morny.—This, although an old kind, is one of the best of zonals for small beds, inasmuch as it is of a close, compact habit and very floriferous. The colour, too, is peculiarly soft and pleasing, and serves to tone down the more brilliant kinds. For pot culture it is very suitable, more especially for late autumn decoration.—J. B.

The Fennel-leaved Fern.—I think "J. C., Byfleet," is mistaken about the name of the above. The Fern which bears most resemblance to Fennel is Asplenium viviparum. —Styan, *Potternewton, Leeds.*

"The Garden Annual."—This book is now ready, and may be obtained at all Messrs. Smiths' stations, through all booksellers and news-agents, and from nurserymen and seedsmen, price 1s. Those who have sent orders for the book, accompained by remittances, are requested to note that it has only been completed a day or two ago; should any delay in getting copies occur it must be put down to the difficulty of getting the number required printed and bound. Orders for the whole of the first large edition were received before a copy was issued to the trade, and another edition goes to press this week. There will be a separate well-bound edition at a higher price for the convenience of those who wish to preserve the volume or have to use it much.

Robinson's Anemone (A. Robinsoniana).

Variegated Jacob's Ladder (Polemonium cœruleum variegatum). — This fine-foliaged plant is not so much used for flower garden decoration as it should be. For a row near the front of a ribbon border, or surrounding a small bed, it is the prettiest plant I have seen. It grows from 6 in. to 12 in. high, and the leaves are thrown out from the centre stem; they are light green and white in equal parts, and in form they are as delicate and handsome as any Fern frond. I call attention to it now because its beauty in summer greatly depends on how it is treated during the cold season. It will live throughout the winter if left in the ground, but when the fresh leaves appear in spring, they are generally deficient in colour as they come green, and want the fine variegation which is their principal attraction. To avoid this, and retain all their delicate lines, it is necessary to lift the plants at the present time and place them in pots, when they should be wintered in a cold frame. The soil in which they are potted should be very light, and they must be kept just moist, but neither wet nor dry, until spring. Old plants generally emit a number of small crowns, from which the plants are increased. They should be taken off in March, and potted singly in small pots, when, if kept close and moist in a frame, they root quickly, and form healthy plants for turning into the open ground early in May.—H.

Geranium Lord Giffard.—Those who may not have this variety should add it to their collection. It is an excellent bedder, the flowers being crimson-scarlet with a clear white eye, habit good, and flowers as freely produced as one could well desire. When I state that it is highly recommended by Mr. Cannell as possessing exceptional excellenee, I can scarcely say more in its praise.—J. C., *Byfleet.*

ANSWERS TO QUERIES

3871.—**Violets in Winter.**—It is very unusual for Violets to lose their leaves owing to such trifling frosts as we have had up to this time. Probably the snow which fell so heavily not long since has brought about this loss of leafage. It will be well to give the plants a top-dressing of Cocoa-nut fibre refuse, which would be better than ashes, and if this be put with sufficient thickness about the roots and crowns, fresh shoots will be early encouraged. We found that Violets (Russian), the Czar, Victoria Regina (single), and the old double blue, Blandyanum (double blue), Belle de Chatenay (double white), and the Neapolitan stood last winter well, but the Double Queen of Whites and Marie Louise suffered a great deal. No doubt it arose less from the severity of the winter than from lack of sunshine to mature and harden the crowns and foliage.—A. D.

3872.—**Roses not Flowering.**—With several large plants of Gloire de Bordeaux, a Rose that does not bloom, it is worth consideration whether it would not be well to rebud them on the best clean wood with other kinds that would probably flower freely enough, and make good robust growth if worked on such robust stocks. As no information is given as to whether the trees are budded as standards or are on their own roots as bush plants, it is all the more difficult to advise. This is a very common fault of those who ask for special information, but do not give some simple, but important particulars. Select next summer some good clean growth, and bud upon it any kinds preferred, putting some half dozen buds of one kind upon each plant.—D.

3875.—**Foxgloves.**—It would appear that some kind of fungus or mildew must be affecting your Foxglove plants, as the complaint of the leaves turning black is an unusual one. We find our Foxgloves are in luxuriant health, the leaves green and vigorous, although transplanted but recently. In your case all depends upon the condition of the hearts or centres of the plants. If these are gone the plants will be useless for next summer, or should they throw up late side shoots these would give but small spikes of bloom. We sow Foxglove seed under glass in April, and get the young plants pricked outdoors when strong enough. These make splendid bunches of leafage, and do not suffer from the weather in any way. If you are apprehensive of losing your plants where they are, it would be well to relift them and lay them in a sheltered spot until March, and then replant where they are wanted to bloom.

3876.—**Insects Eating Ferns.**—The insects that attack your Ferns are no doubt woodlice, as these at this time of the year will feed upon any vegetable substance they can find, but would probably leave Fern fronds at another time of the year for more acceptable diet. If it is not these, then there must be some grub or slug about, but it is most probably the former. They are difficult to catch, unless specially sought for, as they feed only at night, and often if a light appears curl up and become almost invisible. They may often be found in the day beneath pieces of tile or slate, and may be trapped beneath halves of Potatoes laid on or about the plants.—A. D.

3864.—**Covering a Vine Border.**—Covering the Vine border with hot manure a this season was an unfortunate mistake. The young spongioles near the surface were injured, the leaves gave way, and the fruit shrivelled. If the temperature of 60° to 70° named is the night temperature, it is full high for this season of the year. Now the leaves are gone the temperature should be lowered to 50°, or even less, and in future use a little fire in spring, instead of having to fire so sharply in autumn. All Grapes should be ripe now.—E. H.

3873.—**Holes for Fruit Trees.**—Your friend is right; the holes should have been made larger and the soil well worked. In point of fact, I would rather, if the case had been mine, have trenched the ground all over 20 in. deep, cultivated the surface a few years, and then laid it down again to Grass. I do not like planting young trees in old orchards unless this matter is well attended to.—E. H.

3758.—**Ferns for Miniature Fernery.**—"C. B." wishes for a list of Ferns suitable for a small Fern pit. I would advise him to prepare his rockery as would suit his own fancy, as I think no one could give a definite plan for such a small Fernery, only I would say that in making it the rougher the work is performed the more picturesque it will look. Adiantum Capillus-veneris, Asplenium nigrum, A. Ruta-muraria, Allosorus crispus, Ceterach officinarum, Blechnum spicant, Polypodium dryopteris, Polypodium alpestre, Selaginella spinosa, Polypodium vulgare. The following are larger and stronger-growing varieties, retaining their fronds more or less through the winter until new ones begin to shoot up: Lastrea æmula, L. Filix-mas, Polypodium Filix-fœmina, Scolopendrium vulgare, S. v. var. crispum, S. v. var. laceratum, S. v. var. marginatum, S. v. var. multifidum, S. v. var. polyschides. It may not be out of the way to remark that by fastening up pieces of turf to the walls, a good variety of seedling Ferns may be expected, especially of the Scolopendrium tribe.—T. Lowe, *Penketh.*

3885.—**Pruning Climbing Roses.**—We should prefer to leave any systematic pruning of climbing Roses till the spring, when if any injured or other useless growth needs removing it may be done. The best time for this would be about the end of March. Climbing Roses, however, require to be very sparsely pruned as a rule. The robust shoots often made should be tied in and preserved, and only just shortened back. The weak shoots that will perhaps produce no flowers may be taken out altogether, as this will help to strengthen the remainder. Although the shoots need not now be pruned, they will be all the better if tied up neatly, and will suffer less from frost. The chief danger from frost to newly-planted Roses lies in the roots and the collar, or stem just out of the ground. A little protection with some litter will be of great service.

3886.—**Plants for Hanging Baskets.**—Very much depends upon the temperature in which hanging baskets are to be kept in advising as to the best plants to fill them, and certainly no baskets should require to be filled more than twice in the year, say in spring and autumn. The Ferns used should be small, such as Pteris serrulata and tricolor, Adiantum cuneatum and graeillimum, and Davallia Mooreana and bullata, both creeping kinds. Of other plants, the Ivy-leaved Pelargonium, creeping scarlet Tropæolums, Torenia asiatica, several Mesembryanthemums, Petunias, and Heliotropes make good summer plants. For winter, Epacris gracilis and herbacea, Echeveria retusa, Vinca elegantissima, variegated Myosotis dissitiflora, Iberis correæfolia, Lithospermum prostratum, Aubrietias, and Alyssum saxatile are all hardy.—A. D.

3882.—**Keeping Frost from Evergreens.**—All kinds of trees that are growing in soil that is wet and cold must have of necessity much more difficulty in maturing and ripening the season's growth than where the soil is dry and warm. It is an evil that is inevitable from the situation. In such case, growth that is unripe and sappy will suffer very much from severe frost, whilst growth on trees or shrubs of the same kind in a better position will not be injured in the least. If the shrubs were lifted in April and slightly elevated, it would check the growth, and perhaps that would become well hardened ere the winter set in. The next best thing to do is when severe frost sets in to draw the heads of the Bays and Laurels together with stout cord and give the protection of a few bast mats. These, however, should be put on only when severe weather promises, and be removed as soon as danger is over. Perhaps we may have no more such dangerous winters for several years.

3883.—**Lilies and Forget-me-nots.**—In carpeting a bed of Lilies with Myosotis dissitiflora it is not absolutely necessary that the carpet plants should be removed each year. This Myosotis is usually good for two years if the first plants are seedlings. The Lilies should, however, be planted deep, that is, quite 9 in. below the surface, as the Myosotis will pretty well exhaust the soil to a depth of 6 inches. We should prefer to remove the carpet plants every autumn, refork the surface, at the same time adding a dressing of rotten manure and leaf soil, and replanting seedling plants for a carpet. If ordinary care were exercised, we fail to see how the Lily bulbs would suffer. All depends upon the depth at which they are planted.—A. D.

3874.—**Pruning and Training Vine.**—The young Vine being required to fruit next season, and purchased for that purpose, is doubtless well ripened. It is no doubt also planted in good turfy soil, and the stem, if any part be exposed, should be covered with dry litter, thatching the roots also with the same. If the cane should not be well ripened its whole length, or if its permanence is of more consequence than a heavy crop of fruit the first season, then it will be better to cut it back more or less, according to its strength and the number of bunches it may be desired to take—from a third to a half will perhaps suffice. Just before the sap rises—say in February—bend the cane back towards the front of the house to make the bottom eyes break well. Twisting the young cane round on the hand till it snaps often hastens the breaking of a sluggish Vine. I suppose no forcing will be attempted beyond what can be done with sun-heat obtained from early closing in the afternoon. As the buds push in March, use plenty of moisture in the atmosphere. Ventilate early in the morning on fine days, shutting up early in the afternoon. If more than one shoot starts away from each joint, remove the weakest; only leave one bunch of fruit to each shoot. Train the main rod about 15 in. from the glass, and tie down the fruiting laterals as they require it, drawing them down gently at first, or they may snap off. When they have extended two leaves beyond the bunch, nip out the point of the shoot, and pinch out the points of all sub-laterals when one leaf has been made. During the spring, much will appear in the "Calendar" to meet your case. Read and think.—E. H.

3862.—**Hedge for Garden.**—Willows on the banks of a pond would not be unsightly; they grow quickly and soon afford a good deal of shelter. Plant the golden Willow thickly, and in addition plant two or three tall standard Weeping Willows in the hedge; then the Willow hedge will be both a useful and a pretty feature. The Willows may be cut back occasionally, and their trimmings be turned to some useful purpose.—E. H.

3725.—**Forcing Asparagus.**—Make up a good hotbed of leaves and stable manure in order to have a nice gentle heat. As the leaves retain heat longer than manure, it is well to mix them where both can be obtained. After turning the bed over to let the rank heat out, place on about 4 in. of good rich soil. Four-year-old roots are the best for forcing, provided they are well grown. Cover rather deeply with the same kind of soil, and give a light top-dressing of salt and soot. But to grow Asparagus well it requires a good brick pit with artificial heat, either hot-water pipes or flues, for top-heat in addition to the hotbed already advised. I should also add sufficient water must be given to keep the bed from becoming dry; the temperature may range from 60° to 65°.—T. Lowe *Penketh.*

3885.—**Pruning Climbing Roses.**—"A. W. S." does not give the names of the climbing Roses. If Hybrid Perpetuals, leave them alone until March, when cut back to a vigorous eye, thinning out all weakly and misplaced shoots. If Teas, do not prune until April and then only sparingly, retain the well placed ripe wood intact, cutting away the rest. The frost having nipped the ends of the shoots will not matter, but Teas and Noisettes should be covered up in severe weather. H. P.'s will not harm. Give both a good mulching of manure at the roots.—W. Walters, *Burton-on-Trent.*

3878.—**Camellias from Cuttings.**—It is now too late to strike Camellias; the proper time is in August just as the wood matures. The cuttings should be taken from the young free shoots of the current season's growth, cutting them to three joints, and leaving the two terminal leaves. Prepare some 6-in. pots by filling them to one-third of their depth with drainage, covering the same with rough peat, and filling quite to the rim of the pot with fine, well-sanded, fibrous peat, tapping the pot down sharply on the bench, so that it settles firmly into place. Give two moderate waterings at an interval of an hour or so, when the cuttings are inserted, and having allowed the superfluous moisture to drain off, place them in a cold frame on an ash bottom, or on slates or tiles, so that worms cannot enter. Keep the frame close for a few days and then give a little air every

morning, closing about eight o'clock, and shading from bright sun. If the nights are exceptionally warm and still the light may be altogether withdrawn, as the cool refreshing night dews will do much towards preserving the foliage in health. If the atmosphere is too confined, the leaves are apt to turn yellow and drop. By the latter end of September the cuttings should be removed to a glass structure, where the temperature will be maintained at from 50° to 55° throughout the winter. They should be placed in a frame or hand-light, so that when air is given in the house they are not in any way exposed to its influence. At the same time a change of air must be given them daily by removing the glasses for an hour or two early in the morning. Attend carefully to watering, keeping the soil moist, but avoiding heavy waterings. By April, roots should be formed, and the young plants may be potted off into small pots in a compost of loam and peat in equal proportions.—J. C. B.

3866.—**Culture of Romneya Coulteri.**—This Californian Poppywort demands liberal treatment to bring it to perfection. It likes a free, deep, tolerably rich, but well-drained soil to grow in, and will then make rapid progress. We would recommend that the seed be sown in March in gentle warmth, pricking off the plants when large enough to handle into pans of free soil, hardening them off in a cold frame, and planting out in May in a warm, somewhat sheltered situation.

3863.—**Vegetables for Exhibition.**—Celery—Incomparable White, Sulham Prize Pink, and Hooley's Conqueror Prize Red. Onions—Magnum Bonum and Improved Reading. Leeks—Ayton Castle Giant Beet—Nutting's Dwarf Red. Turnips—Cattell's Silver Ball. Carrots — Early Nantes and James' Scarlet. Brussels Sprouts—Suttons' Matchless. Cabbage—Heartwell Marrow and Enfield Market. Savoy—Dwarf Green Curled. Cauliflower—Veitch's Autumn Giant and Suttons' King. Parsnips—Student. Rhubarb—Myatt's Victoria. Tomato — Hathaway's Excelsior. Vegetable Marrows—Moore's Vegetable Cream. Peas—Telephone and Ne Plus Ultra. Beans—Seville Longpod. French Beans — Canadian Wonder. Scarlet Runner—Carters' Champion. Cucumber—Telegraph.—E. H.

3865.—**Iris Kæmpferi.** — This Iris is perfectly hardy in free, warm, well-drained soils, and when thus situated does not need the slightest protection. Where the natural staple is cold and heavy, it would be well to protect the crowns by a covering of ashes or Cocoa-nut fibre. Fairly strong plants should bloom next year, but a season's growth will be required before any great effect is obtained. Mulch in the summer and water well in dry weather; this Iris likes plenty of moisture at the roots. —J. C. B.

3867.—**Malformed Chrysanthemum Blooms.**—There are many causes for Chrysanthemum blooms coming of an imperfect shape. Immature wood will alone suffice to prevent their coming good, as will also want of water, mildew, or torpidity of the root. The fact of your blooms being small shows that the plants have not had the treatment they need, and we should say that they have suffered from want of water and food. Read some of the articles on Chrysanthemum culture which have appeared in this paper. Give your plants liberal and intelligent treatment, and you will not have again to complain of bad flowers.—C. B.

—— After the instructions given last week for the cultivation of the above plant, it is scarcely necessary to add any further remarks on the subject. However, the probable cause of your flowers being small and deformed is that you allowed the plants to become dry or root-bound at times during summer. No subsequent treatment will compensate for neglect in this respect during the growing season. The production of good flowers necessitates constant attention at all times. The Chrysanthemum is also liable to be affected with green fly, which however slight, if not stopped is fatal to the formation of perfect flowers.—CARLO.

3854.—**Transplanting Holly.**—I would strongly urge that Holly be not transplanted until April. There are only two seasons when this evergreen can be moved with perfect safety —early in the autumn, before root action has come to a standstill, and in spring just before growth commences. In the case of a Holly hedge, established two years, great danger would be experienced in transplanting it during the winter season; probably a fourth or perhaps more of the plants would die. The best way will be to well prepare the ground for its reception during the winter; choose if possible a moist time in April, transplant, well mulch the surface soil, and water copiously in hot weather. If the weather is dry, dip the roots of each plant in water before planting, and water each one well in. In this manner not one plant in a hundred will suffer. It is imperative in the case of the Holly that it strikes fresh root at once, otherwise the sap dries out of the foliage and it drops before a fresh supply can be pumped up.—J. C. B.

3881.—**Unfruitful Cherry Tree.**—Judging from the symptoms described, the roots of the Cherry tree are down in the cold subsoil. Can they be lifted and brought nearer the surface? If this cannot be done, cut out some of the old branches and lay in young wood that may be left to fruit its full length.—E. H.

3868.—**Mulberry Tree not Fruiting.**—The Mulberry tree ought to bear well at that age. Is it shaded by other trees? If it is growing too luxuriantly, and the wood does not ripen, try pruning or lifting the roots; about half way round this year, and the remainder of circumference next year if the check does not produce the desired effect.—E. H.

3821.—**Myrtles from Seed.**—Sow in March in sandy loam, well draining the pot or pan employed, and placing it in a cold frame or cool greenhouse. Cover the pot with a piece of glass, and shade until the young plants appear above ground.—J. C. B.

3741.—**Pruning a Young Vine.**—I would advise "E. M." to cut the main shoot of the Vine, so as to leave 3 ft. or 4 ft. to the roof of the house. The Royal Muscadine being of very weak growth, three eyes to the side shoots may be left, provided they are not too long and unsightly.—T. L

3819.—**Ants in Greenhouse.**—Lime-water poured freely into their runs will dislodge them.—CYGNET.

3825.—**Removing Glass from Greenhouses.**—Soft soap mixed with solution of potash, laid on with an old rag and left for some hours, will render the old putty removable.—CYGNET.

3876.—**Insects Eating Ferns.**—Very probably it is a snail. Look under the pot by candle-light.—CYGNET.

3877.—**Old Roses.**—Messrs. Cranston & Co., King's Acre Nurseries, Hereford, or Messrs. W. Paul & Son, Waltham Cross, will supply the old Roses required. The Alba Roses, Austrian Roses, &c., are to be found fully described in their catalogues, and I would advise "S. E." to procure a catalogue from one or both of the firms referred to.—WILLIAM WALTERS.

3872.—**Roses not Flowering.**—I cannot do better than refer J. Lacy to my reply to No. 3402, page 432, Nov. 6, 1880, where I endeavoured to point out the treatment of Gloire de Bordeaux and similar rapid-growing Tea and Noisette Roses.—WILLIAM WALTERS.

3940.—**Arbutus Unedo.**—*F. Baker.*—You might strike cuttings of this in August. It may also be raised from seed. Your best plan would be to purchase a few young plants; they are not expensive.

3941.—**Standard and Dwarf Roses.**—What advantage has a standard Rose tree over a dwarf that the price is greater? Also, will the ordinary dwarf or standard Rose trees advertised in Rose lists grow if put in pots in a greenhouse?—F. J. L. [The standard Roses take a longer time to convert into saleable plants than dwarf ones do. Standards have no particular advantage over dwarfs. Either will grow in pots in a greenhouse.]

3942.—**Cupressus elegans.**—*A. E. A.*—If the plant is only green on the top dig it up. A withered tree with a little green on the top is certainly not ornamental. You might plant some Clematis against it and let them grow over and cover it.

3943.—**Stokesia cyanea.**—*S. S.*—This, the popular name of which is Stoke's Aster, is a stout, free-growing herb flowering in September. Its flowers are blue, and somewhat like those of a China Aster. Warm borders suit it best, or it may be grown in pots in a greenhouse. It is increased by division of the root.

3944.—**Forcing Roses.**—What time might I introduce Roses into the forcing house to have them in bloom about April 15?—YOUNG GARDENER. [Put one batch at once, and another in a few weeks' time, in a cool house or frame, and let them come gradually on. When the flower-buds show put them in the forcing house.]

3945.—**Dahlias for Exhibition.**—How are Dahlia flowers protected so as to have them fresh and fully expanded for exhibition?—YOUNG GARDENER. [They are usually cut on the morning of the show and sprinkled with water.]

3946.—**Chicken Manure** —*Amateur Fowl Keeper.*—Fowls' manure is very good for gardening purposes, but unless you can use it yourself or dispose of it in your immediate neighbourhood it will be of little value to you.

3947.—**Geraniums and Azaleas.**—*M.*—Geranium cuttings do not require much water during winter; give a little when the soil gets dry. Azaleas want plenty of water, but it should not be given often in dribblets, but in large doses when the plant requires it. They will do well in a cool house, or may be forced into flower in a warm house.

3948.—**Heating Greenhouse.**—What amount of 4-in. piping would it take to heat a lean-to greenhouse 9 ft. by 5 ft.?—AMATEUR. [If merely to keep out frost, a flow and return along the front will be ample; if for forcing, &c., put a flow and return all round.]

3949.—**Climber for Greenhouse.**—I have a greenhouse 10 ft. by 6 ft., in which I keep a general variety of bedding plants. The floor is of concrete, with one open space 15 in. square against the back brick wall. What will be the best plant or Vine to grow in it for training up the wall and under the glass roof?—T. E. HORWELL. [Plant a Maréchal Niel Rose.]

3950.—**Manuring Vine Border.**—My Vines are planted in an outside border, which is not more than 3 yds. wide. The Vines are very old, and have been very much neglected; they are not trained at all, but run wild. I have given the border a good manuring, and covered with long littery manure. Would you recommend me to give the border some liquid manure, as I have plenty, such as the drainage from the farmyard? Is this the proper time to apply it?—NOVICE. [We should not give manure water till the Vines begin to grow. During summer you may give the border a good soaking once a fortnight, or oftener if it is well drained. Cut out some of the weakest wood where too thick, also the unripened shoots, and prune back the strong shoots where necessary.]

3951.—**Vegetables in the Shade.**—I have a bed of soil which is very much shaded. I want to grow some vegetables; which will be the best for me to grow?—E.F. [Lettuce, Winter Greens, Sprouting Broccoli, and Turnips.]

3952.—**Vegetables in Shallow Soil.**—I have an unused well in my garden; I have covered it with boards, and have about 8 in. of mould on the top. I want to grow some vegetables; what will be most likely to succeed?—E. F. [Turnips, Radishes, Early Horn Carrots, Onions, or any surface-rooted plant.]

3953.—**Tiger Lily.**—I planted one of these in my garden in 1878. In the summers of 1879-80 it did not flower; of course I left it in the open ground all the year round. Last October I took the bulbs up, intending to plant some in the open ground again, and some in pots to be kept in the house. How must I now proceed? when and how must I plant, kind of soil, size of pots, &c.?—PHILFLORA. [Well dig and manure the ground, and plant 4 in. or 5 in. below the surface. If you can keep the bulbs in a dry, cool place you may plant them in spring. Those for pots should be planted at once in turfy loam or peat and rotten manure or leaf-mould with plenty of sand added; 6-in. pots will do for single bulbs, or two bulbs may be put in an 8-in. pot. Give good drainage.]

3954.—**Fuchsias in Rooms.**—I cut my Fuchsia back last September, and placed it in a shady place under a window in one of my rooms, giving it a little water occasionally. It has now sent forth numerous shoots, some of them 3 in. to 4 in. in length, but drawn. What ought I to do with it?—PHILFLORA. [Put it in a light, airy position, and keep it dry till spring; then pinch back the weak growths.]

3955.—**Transplanting Cactus Cuttings** —*H. W.* —It would be best left till spring.

3956.—**Moving Rose Cuttings.**—Unless you have a warm frame or house to put them in, it would be better not to move them now. As they are in the same pot as a Fuchsia, it would be better to sacrifice the Fuchsia than the Roses.

3957.—**Planting Vines.**—When is the best time to plant Vines? and where can I get a good Black Hamburgh? and about what price?—GRAVESEND. [Plant now. If for outside border plant in open weather, and mulch the roots with half-rotten manure. You can get a good cane at any respectable nursery where Vines are grown: price about 5s.]

3958.—**Mineral Oil for the Destruction of Blight.**—*R. F. S.*—This is always best applied to plants in autumn when their growth is well matured, as they will then stand the mixture much stronger than at any other time. If applied in spring when young plants are being made, it is best to apply the oil weak and at intervals of a few days. You will do no good with mineral oils in destroying slugs in a garden.

3959.—**Raising Young Ferns.**—How can I raise young plants from a Fern which has made new leaflets on the fronds of an old plant? C. S. S. [Peg the old frond into a pan filled with sandy soil.]

Tuberoses.—*Mr. G., Dover.*—You may get them from any respectable seedsman. See our advertising columns. We cannot state the price.

Italian Prune Plum.—*S. W.*—You will probably get it at any of the large fruit nurseries. Try Hill (late Scott), Merriott Nurseries, Crewkerne.

Copying Machine.—*Hereford.*—We think the receipt given July 3 will answer your purpose.

Achillea umbellata.—*Subscriber.*—From any hardy plant nursery, such as Ware's, Backhouse's, Parker's, or Dickson's.

Hardy Ferns.—*Cygnet.*—An answer to your query would be an advertisement.

Names of Plants.—*We cannot undertake to name what are termed florists' flowers, which include Pelargoniums, Fuchsias, Roses, Chrysanthemums, &c. These can only be named by specialists who have the means of comparison at hand.*——*Nine Months' Subscriber.*—1, Erica nitida; 2, E. gracilis; cut back after flowering; re-pot when new growth commences.——*W. T. K.*—Probably the Hand Plant (Cheirostemon platanoides). We do not know the hedge plant you mention.——*Singleton Fontenoy.*—Probably you mean Pelargonium teretifolium. ——*Subscriber, Plumstead.*—1, Anthoxanthum odoratum; 2, Cynosurus cristatus; 3, Holcus lanata; 4, cannot name; 5, Festuca pratensis; 6, Linum catharticum.—— *F. H.*—Ionopsidium acaule.——*F. A., gardener.*—Amomum cinnamomum.——*W. Cash.*—1, Abies Alcockiana; 2, A. ajanensis.——*G. D. H.*—2, Cineraria maritima; 4, Coronilla Emerus; 6, Stachys lanata; Vaccinium bxifolium (red berries); send better specimens of others.

QUERIES.

3960.—**India-rubber Plants.**—Can any one tell me how I should treat my India-rubber plant? I had one in my drawing-room for a little time, but the lower leaves soon turned yellow and fell off. I have now got another, and shall be glad to know how I should treat it. I have no other place to keep it than the window.—C. A. T.

3961.—**Scale on Vines.**—I have two large Vineries which are very much infested with scale. I have tried various means to destroy it, such as scraping the Vines, painting them with Gishurst, 6 oz. to the gallon, &c., but without success. I am recommended to try paraffin along with the Gishurst. Could any one inform me what quantity of paraffin to mix with the Gishurst? or suggest any other remedy for destroying the scale?—NOVICE.

3962.—**New Potatoes.**—Will some one give me a list of new Potatoes that came out in the year 1880? also their habit of growth and their table quality?—G. B. C.

3963.—**Roses in Pots.**—I have two Roses in pots—one Gloire de Dijon, the other a dark one which I cannot name. Both are Briers and small. The first made only a few buds during the past season; the other made fairly good shoots, which I cut back in autumn. I have them in a warm greenhouse, and they are now breaking well. The temperature is seldom or never under 50°. What treatment should I give them to get them to flower next year?—J. R. S.

3964.—**Pruning Roses.**—I had some Gloire de Dijon Roses, standards, planted last spring; they only bore two or three flowers, but made strong shoots about 8 in. to 14 in. long; how far must they be cut back? and when is the time? I also planted last month some climbers of the same species on the front wall of my house, south-west aspect; they have four to five strong shoots 20 in. to 38 in., Must they be trained straight up or in fan shape? and when and how must they be pruned?—A. K.

3965.—**Maggot on Cabbage.**—My garden soil is full of small white maggots which eat all the roots of Cabbage, Sprouts, &c. Can any reader suggest a remedy?—CABBAGE.

3966.—**Lime, Soot, and Salt for the Kitchen Garden.**—I have a garden about 18½ rods. I have just put 1½ cwt. of salt on it. Will someone be kind enough to tell me if lime and soot will be of any service to the ground, as I want to get some good Potatoes. If so, what quantity should I want?—C. B.

3967.—**Weeds on Lawns.**—My lawn appears to have been originally sown with very inferior seed. It has gradually got worse and worse, and is now foul with all kinds of weeds. Of course, to redig and sow with good lawn seed would be the best way to get rid of the nuisance, but is there no way I could kill the weeds, &c.? Would raking well with a strong iron rake, spreading sulphate of ammonia on it, letting lie till spring, then again raking, sprinkling good lawn seed, and slightly covering with good soil be likely to do any good?—E. W. C.

3968.—**Banksian Roses not Flowering.**—Four years ago I planted two Banksian Roses against a west wall; they made good wood, but have not flowered. What can I do to them?—AMATEUR.

3969.—**Cropping a Garden.**—In my garden, which is a deep light loam, I purpose devoting about fifteen rods to early Potatoes and Brussels Sprouts. I shall now have the ground trenched and a good dressing of manure worked in between the top and second spit, soot and lime being mixed with the manure in filling the barrows. When the Potatoes are planted the ground will be forked, and a dressing of guano given to the Potatoes in rows 2 ft. apart, the Brussels Sprouts being sown early and planted between the rows of Potatoes after earthing. Will this be good practice? and what quantity of guano will be required for the fifteen rods? Would it do good to give a slight dressing of soot after the Potatoes are up before planting the Brussels Sprouts? Is brine from a bacon-curer's good for crops? and when should it be applied?—ENQUIRER.

3970.—**Summer Snowflake** (Leucojum æstivum).—I have some seed of this; which is the proper time to sow it? and what is the best after treatment for it?—INQUIRER.

3971.—**Melons and Figs.**—I wish to grow these in a greenhouse heated with hot-water pipes. I should be glad to know if they would fruit if grown in pots and trained up the spars? Any information concerning the above would be appreciated.—T. G.

3972.—**Pruning Clematis.**—Will some one inform me what is the best time, and more particularly the best mode of pruning back a Clematis? Mine is a rather large single star-flowered kind, not one of the new large flowering sorts. It grows very luxuriantly, makes a great deal of wood, and spreads very widely, so that if one cuts out any of the large woody stems, one does not know how much space will be laid bare, and if the young wood is cut back, I lose in the spring the pretty sprays of flower 3 ft. or 4 ft. long; how is this to be avoided; and yet the plant kept within moderate dimensions?—A PUZZLED AMATEUR.

3973.—**White Worms in Soil.**—Will any reader tell me what I can use to destroy numbers of very small white worms which I find in the mould at the roots of my Maiden-hair Ferns? They cause the fronds to wither and die.—FORGET-ME-NOT.

3974.—**Rhododendrons.**—I should fell obliged if some one would give me a short list of the best kinds of Rhododendrons, and the kind of soil and situation required to induce them to flower well.—G. B. B.

3975.—**Pancratium carribbæum.**—I have several bulbs of this, and should be glad to know the proper treatment at this time of the year. Mine are rotting off; they are in a greenhouse at a temperature always at 60° or 65°.—MALDEN.

3976.—**Building a Greenhouse.**—Having seen the remarks of "G. S. C." on this subject, and that he now offers to give fuller particulars, I write to ask you for such information as would enable me to judge of the cost. Perhaps he could tell me what it ought to cost per each item for a house, span-roof 15 ft. long, 9 ft. wide, 8 ft. high, but only 3 ft. at the sides, including brickwork of 8 in. I propose sinking the path in the centre 3 ft.; in fact, making a forcing pit in which I could grow Cucumbers or Melons. Being an amateur carpenter, I should like to do the work myself.—C. C. OLDFIELD.

3977.—**Newly Planted Roses.**—The Roses we get from the nurseries are often very deficient in root and fibre. Should not this modify the rules for pruning in the spring following the autumn planting? My Roses, fresh bought and planted in the autumn of 1879, did not flower well or grow last summer, though well fed. I pruned the vigorous ones rather long, as the books direct. Should I not have done better by cutting them back more severely in March?—S. L.

3978.—**Heating a Wardian Case.**—I have a Wardian case which I have tried to heat, the apparatus simply consisting of 1½-in. tin piping going through the case, and being heated by a lamp, the globe fitting in a tundish outside the case. The pipe is perfectly air-tight, so that the fumes cannot escape. I cannot get it above three degrees of the ordinary temperature, and the Ferns of late are dying off and looking black.—NOVICE.

3979.—**Dwarf Hyacinths.**—Will "W. B." who writes in GARDENING ILLUSTRATED, No. 81, about dwarf Hyacinths of the sort which "feather" from Holland, kindly say where they are to be got?—K. M.

3980.—**Canary Seed for Producing Room Plants.**—I have been told that by sowing Canary seed one can very quickly obtain pretty pots of green for the room. I shall be much obliged for some information how to manage it.—P. M. F.

3981.—**Hastening the Decomposition of Manure.**—Would any reader inform me if there is anything that will hasten the rotting of stable dung without diminishing its manurial properties.—A. B. W.

3982.—**Planting Fish Pond in Fernery.**—I have an exotic Fernery about 10 ft. by 8 ft., with a small but irregular-shaped fish pond, 8 in. deep and about 18 ft. superficial in extent. I want to introduce some aquatic flowering plants and fish. Would any reader kindly inform me how many and what sorts of each are the best and most effective for the purpose?—MERCATOR.

3983.—**Best Show Chrysanthemums.**—Will some one tell me the names of twelve of the best show Chrysanthemums in cultivation?—W. J.

HOME PETS.

Singing Mice.—I have heard and seen singing mice, but do not know that they are in any way trained or offered for sale. It is supposed that the little animals which show the musical peculiarity merely do so because suffering from some painful physical defect, but it is not obvious to the ordinary observer. The music is like a sort of whispering, monotonous melody, much as the bagpipes would make if heard at a long distance. In both the cases where I have met with these mice it was in rather old houses, where there were good runs in the walls and behind the skirting. I shall be interested to learn that such mice are offered for sale.—A. D.

Parrot with Sore Throat.—Not having seen any remedy given for the above, I would suggest feeding her with bread and milk, and giving Hemp and Canary seed sparingly. My experience is that parrots do not care for Indian Corn, even boiled as it should be for an hour. I have a parrot of this year who is perfectly healthy; her food consists principally of boiled milk and bread, and when the warm sloppy mess is given her, she makes the best meal of the day.—R. H.

Parrot Poisoned with Parsley.—Whilst travelling this year I met a lady whose valuable parrot had died from eating Parsley. The cook, although previously warned of its effects, gave her some, and she died in a few hours, having vomited some of the herb.—R. H.

Canaries with Long Nails.—Very carefully clip just the tips of the nails with very sharp small scissors. Great care must be taken not to cut too much off to make the nail bleed, or it will lame the bird. The best plan is always to keep two or three rough stones at the bottom of the cage; the constant hopping upon them will keep the claws properly worn down.—P.

Changing the Colour of Canaries.—I have a very pale yellow canary, and I have heard that cayenne pepper would make him a darker colour; is it true? and would it do him any harm?—MERVYN.

Insects in Birds.—I have a Virginian nightingale (Cardinal Grosbeak) which seems to be greatly troubled by insects of some sort or other, and thought of sprinkling him with Keating's Insect Powder, but I fear he may, in "teasing" his feathers, peck at the powder, and so poison himself. I should be obliged if anyone can, from his own experience, give me some information on the point.—MYRA.

Budgerigar Losing its Feathers.—My cock Budgerigar in two days lost nearly all the feathers off his head, also a narrow line of them from between its shoulders. The complaint appeared to begin there, and the bird appeared unwell about a week previously. Is there any cure? He appears to search for something in the sand; he has both yellow and silver sand; would gravel be safe to give? It is fed on Millet, Canary, Plantain, and fresh Grass.—M. B. A.

Parrot Mopish.—I have a parrot which used to talk well, but lately it has gone off talking and sits and sleeps nearly all day. He takes his food well, which consists of Canary and Hemp seed, with sopped bread. Can any one tell me what course to pursue to make him more lively and resume talking?—E. K. G.

AQUARIA.

Plant for Small Aquarium.—Would some one give me the name of an aquatic that would do well in a small indoor aquarium? I have tried Vallisneria and the Cape Pond Weed, but they do not succeed. Also where I could procure a small self-acting fountain for same?—AQUA.

Stocking an Aquarium.—I have in my greenhouse, which has a south-west aspect, a large vase (earthenware), 2 ft. in diameter at the top, and originally intended to be used as a flower vase, and has now two gold fish in it. I wish to stock it. Will some reader of GARDENING ILLUSTRATED advise me how to proceed? It has no plants in it, in fact, nothing but the two fish. D. S. A.

Cement for Rockwork.—Portland cement may be changed to any colour you like. Lamp black will make it black, yellow ochre will make it yellow, and if "R. S. W." went to any good colour shop, they would supply him with colouring matter to any tint he may wish.—FERNDALE.

GARDENING

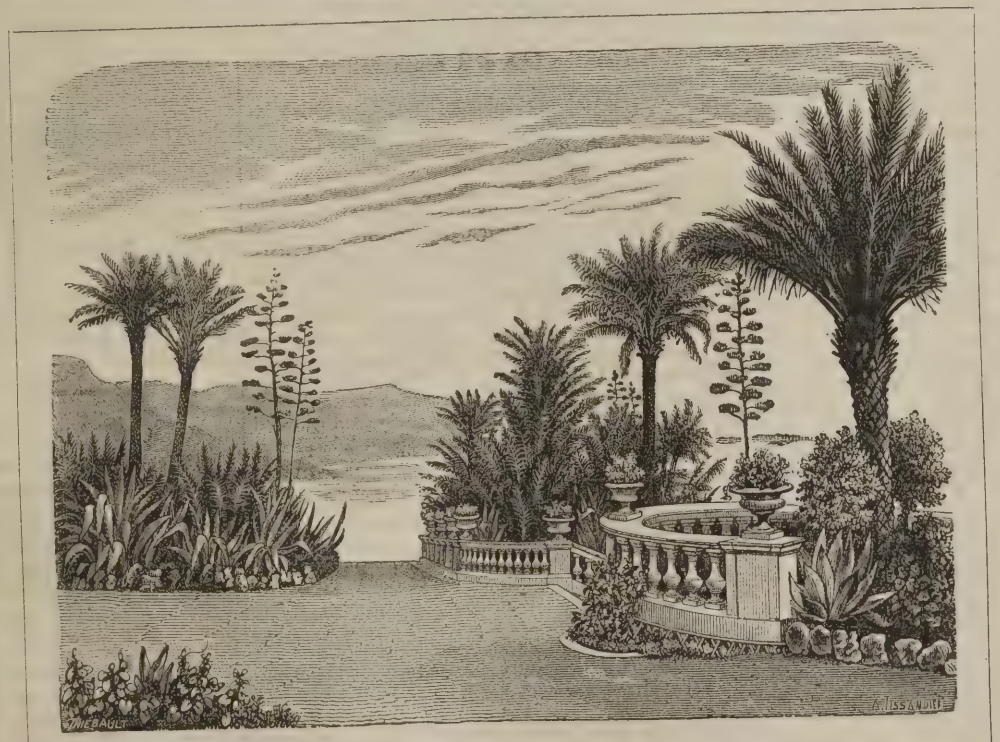
REGISTERED FOR TRANSMISSION ABROAD.

WINTER GARDENING IN EUROPE.

FEW people are probably aware that whilst our own gardens are denuded of their greenery and flowers, and whilst we are shivering with the cold, there are, within twenty-four hours' ride of our own shores, beautiful gardens of Palms and Aloes, and in our climate other tender plants, in which reigns almost summer weather. We allude to Riviera. Nice, and other places in the south of France. To give some idea of what the gardens there are like in winter, we reprint a portion of some letters written to us about this time last year, by a gentlemen staying in the South of France:—

"I am writing by a window wide open in the hot sunshine and under a bright blue sky. I look through the window, and I see that huge Cactus, the Prickly Pear, full of fruit, four large specimens on one leaf, and close by a Lantana, with its gay red and yellow flowers, occupies a space about 14ft. in height by 10ft. in breadth. Some of the upper branches have left the wall and are drooping over an Orange tree laden with golden fruit. Next to this there is an Arbutus (which ripens its Strawberries so thoroughly here that the tree must no longer be called Unedo; eat one and you will want no more, because they are good for food, both preserved and *au naturel*)—a great tree full of blossom; and beside it the Japanese Medlar, also showing abundant promise of fruit. If I go into the gardens of the hotel I find the Datura, with its beautiful white bells; Roses Lamarque, Homère, Bourbon Queen, Mrs. Bosanquet, the Old Monthly, and other Chinas, such as Fabvier and Cramoisie Supérieure, Safrano, Gloire de Dijon, &c., (in other gardens I have twice seen Chromatella or Cloth of Gold); the Heliotrope flowers freely and perfumes the air; Plumbago capensis covers great bushes with its blue-grey blossoms; Acacias and Abutilons are here in profusion; and there are Violets and Carnations, Zinnias and Pansies, Escallonias and Veronicas *galore*. The Polygalas and Chorozemas, which you English tie out in pots, and coddle under glass, and take to exhibitions, grow here to any size you please; and the Palms, which you put on your dinner-table, are great trees 15 ft. high, with their Dates hanging down in huge bunches on their red stalks. Do you remember a plant of Bougainvillea glabra, which you showed me in your stove, proudly pointing to its flowers, few in number, in complexion pale? I saw it yesterday covering a coachhouse. It really made me for a few moments feel faint and ill with admiration. A mass of roseate beauty, with a tinge of mauve or blue—all flower (or rather bracts)—scarce a leaf to be seen. For two or three days it has been so hot in the sun and so cold in the shade, that I have felt, now and then, like the *pain roti* which we have at breakfast, and which is sometimes sent toasted brown on one side, white on the other, and untouched by the fire; and at the present the sky is overcast, and a gentle rain is falling (in every clime *some* rain must fall), but the air is so mild, and the foliage so refreshed, that the garden looked this morning as our gardens look on a dull morning in early June. This garden, and the grounds about it, are formed by alluvial deposits, brought by the rivers and mountain streams, and they are protected on the east, north, and west by the hills, which form a crescent round them, or, to use an illustration more congenial to your taste, an horseshoe with the toe turned towards the north; so that we of the suburbs seem to live in one vast garden, or rather in a series of gardens, dotted here and there with picturesque villas, many-coloured, having their walls white, their roofs red, their *jalousies* green (Shakespeare says that jealousy is green), and so fertile that, if your temperament is sanguine and your imagination lively, you may plant the stick of an old parasol at night, and expect to see an Umbrella Pine in the morning. Very abundant and very beautiful in the Riviera are these Umbrella Pines; but what would you say to the Araucaria excelsa, the Pine of Norfolk Island (of which I remember an admired specimen about 8 ft. high in your conservatory) growing up a great tree *al fresco?* How you would delight in the Magnolias, 30 ft. in height, with their vermilion seeds gleaming among the grand foliage; the graceful Pepper Tree, with its Acacia-like leaves, and its red clustering berries, and the Acacias themselves, longiflora and many others, large as your Laburnums, and covered with their yellow flowers. How astonished you would be if I could take you into the city of Nice and show that, which is perhaps the fairest surprise of all, the row of Palm trees with Oleanders in alternation (the former laden with Dates), which extends, with a graceful sweep from the Promenade of the English by the sea to the Place of Massena (so named in honour of the marquis, who was born at Nice), and ending with the noble specimen of Eucalyptus, which, though only planted fifteen years ago, has a trunk and branches such as would not be seen on our forest trees in England in less than fifty or sixty years. Having you in Nice, I must take you up to the Castle, and show you, as we mount the hill, the wonderful Aloes, growing anywhere and anyhow, and, though their inflorescence is over, assuring us by their giant stalks, long enough and strong enough to hold a salmon, how glorious their beauty has been. And as we reach the summit, what a panorama! Let the old man point out the house in the Rue de Smollett, in which resided the author of 'Humphrey Clinker;' and let him show you the home in which Garibaldi was born; and try to sympathise with the Frenchman's pride when, looking eastward over the sea, he tells you that the speck, which on a fine, clear day you may discern, is Corsica, the birthplace of Napoleon! But these surprises are incessant. Palms, encircled by red and white Roses, and by scarlet and yellow Nasturtiums; the blue flowers of the Plumbago intermixed with the crimson blooms of the Bignonia; the exquisite Dahlia imperialis (truly an empress among



A WINTER GARDEN IN THE SOUTH OF FRANCE.

the flowers) nearly reaching the window of a second floor; the Locust tree covered with fruit-blossoms; the Tobacco tree with its yellow tubes; all the flowers I named above, and many others, which, as yet, I have not seen. Can we wonder that such titles as 'Hotel de Paradis' should be selected by the happy innkeepers of Nice, or that the people generally should hold as an article of their creed (Nicene) that the place of their habitation is *La Baie des Anges?* It is no fault of theirs if some of the visitors, especially those who come here that they may gamble at Monaco, suggest very different and less refined associations."

TOWN GARDENING.

Miscellaneous Plants for Outdoor Culture.

Among hardy plants, the ordinary German Iris, or Flag, as well as the wild English yellow one, is about the best for town gardens. It likes a good rich loam and plenty of water when in growth, and it will do well in either sun or shade. The plants flower freely and well, and as the blooms open very quickly, look beautifully fresh and clean. Canterbury Bells, the tall Campanulas, Sweet Williams, and other biennials should be sown in nursery beds or large boxes about July for the next year's flowering, be thinned or pricked off, and if possible, kept in a cold frame during the winter, or protected in some way. Or if this cannot be done, purchase young plants freshly every year; and even in the case of perennials, do not attempt to keep the old plants after they have flowered once, but keep a fresh stock coming on. Any good rich soil, loam if possible, suits them.

Delphiniums are very pretty and flower fairly well, though the lower leaves have a way of dying off which is not at all sightly. The old roots may be left out of doors all winter, as they die quite down; the soil for them should be very deep and rich, and of rather a holding or close nature. Seeds of these sown in July, pricked off into cold frames, planted out as soon as they begin to grow in spring, or even if sown in early spring in a gentle heat, or even cold frame, grown along quickly and planted out as soon as large enough in deep rich soil, and well watered in dry weather, will bloom in the autumn. The best kinds to grow are D. formosum, D. grandiflorum and D. g. cœlestinum, a very pretty variety, and D. nudicaule, scarlet. Do not be discouraged if these look small, and as if they would never come into flower, especially in the early stages. They are a long time making up their minds to make a good start, but when once planted out they grow with wonderful rapidity during the summer.

London Pride and Creeping Jenny planted almost anywhere, especially on rockwork, do very well, and the latter does best in a shady place; it is very pretty for hanging baskets or pots, or window boxes. Primroses and Cowslips are fine, especially the former; plant them in good rich loam in a rather shady place to do best. A plant or two of the former put in good loam in a cold frame will produce plenty of nice clean flowers early in spring, as good as you could get in a country copse or wood, if you give it plenty of air when fine and clear. The Everlasting Pea is very pretty, and as it has an underground bulb or tuber, and the top dies down in winter, it does very well, as, indeed, do many plants that do the same, it is such an advantage to them to be hidden from the poisonous fogs and foul air of the dark days; so that the Tiger Lily, the Turk's-cap, the common garden white, and any hardy Lily almost succeed if planted in deep, rich, and somewhat loamy soil. Be sure to put a handful of sand round each bulb when planting to prevent rotting.

The wild blue Hyacinth, left undisturbed, throws up its bright foliage and flowers every spring, though the colour of the latter is not as brilliant as we see it in country lanes and woods. Crocuses do well too in rich soil, and we have had very decent Hyacinths out-of-doors, but Tulips are more shy. Plant them about 6 in. deep, with plenty of rotten manure down beneath, but not touching them; do not let the surface of the ground where they are, get hard or caked. Marigolds, both the common garden and the French, are very useful. They generally sow themselves, at least the common ones do, and the deep golden and orange, almost scarlet, hue of some of these is very showy. The French are more delicate, and should be sown under glass or some slight protection in spring. The new gold-striped French varieties are really handsome, but we do not recommend the African. Do not omit a few patches, at least, of the lovely Cyanus, or Corn-flowers. Sow the seed in patches or circular rings, with the ground beneath them deeply dug and manured; thin out if too thick, and set three or four slight stakes round the patch with raffia or string tied from one to the other, to keep them up. You will have from a 3d. packet of mixed seed hundreds, if not thousands, of the prettiest flowers imaginable, pure white, white shaded, pink, rose, purple, dark and light blue—more colours than you would care to count.

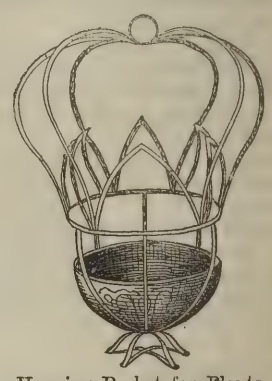
Among annuals nothing beats Mignonette, and it grows to all appearance as well in London as in the heart of Kent. It likes a light open soil, and will do better in such, if pretty rich, than in stiff loam or clay anywhere in the country. Give it a warm sunny border. Silene pendula compacta and other varieties are very pretty and easy to grow; and Venus' Looking-glass and Candytuft are both fine in good rich soil. The lovely Convolvulus major, or Morning Glory, is a great success; it luxuriates in a very light rich soil, such as old decayed vegetable matter. Sow the seed where it is to flower, and do not sow in heat and transplant; it is quite a mistake, but do not sow before April. The finest we ever saw grew on a little heap of old tan at the foot of a south wall in a Bermondsey tanyard.

Among bedding things, Geraniums, Calceolarias, Verbenas, Petunias, Lobelia, the white Cineraria, or Dusty Miller, are the most successful. A great drawback to scarlet Geraniums is that they are apt to go white at the edges of the flowers, which detracts considerably from their appearance, but good cultivation will do much to amend this; another fault is that when in soil suitable for other things, and especially in wet seasons, they are given to make such tremendous growth at the expense of the flowers. The best plan to counteract this is to grow them in 5 in. pots, and just sink them, pots and all, in the ground in their places. This will check the over-luxuriant growth, and induce a free flowering habit, but you must keep them well watered at the root in so confined a space. The Amaranthus, too, is a capital bedding plant of a nice dwarf habit, and the colour of the foliage is splendid, but it is of not the least use attempting to grow Coleus, Alternatheras, Iresines, and other delicate things of this class; these seldom, especially the Coleus, do much good even in pure country air.

With nearly every kind of plant, seedlings are of no use where a number exactly similar in height, habit, and colour are required. No matter how carefully the seed is saved, there is always some slight variation among the plants in some respect. For all such purposes, cutting plants must be had; but for mixed beds and general display, or where a shade or two in the colour is not of much importance, then seedlings are as good, and indeed we consider them preferable for many reasons. If seedlings must be used, and some degree of exactness is required, grow about half as many plants beyond what you really require, and then, if any do not come quite true, you can replace them from the reserve bed. B. C. R.

A New Market.—It may interest your readers to know that an effort is about to be made, through the medium of a joint-stock company or of a limited corporation, to relieve Covent Garden market and the surrounding streets of the congested traffic, by the establishment of suburban markets, the first of which it is proposed to establish on the main thoroughfare between Hammersmith and Turnham-green. This would afford accommodation for the West End, the southern, the western, and the south-western districts on the Great Western road, thereby saving the wear and tear of horseflesh and other costs of transit to many of the Surrey, Bucks, and Middlesex growers; and at the same time enabling the buyers for the north of England and Scotland to avail themselves of the railway facilities, and to purchase goods when perfectly fresh—in fact, upon the day the goods are gathered. As you are probably aware, most of the present West End supply is gathered on the day previous to the market. It is proposed that this West End suburban market should not only be utilised for the sale of every description of market garden and dairy produce, but that on alternate days there shall be sold fish and poultry; also, as the selected site is so spacious, that markets shall be held for cattle to be slaughtered on the spot in slaughter-houses to be specially provided for the purpose.—H. COLES STATITSCHMIDT.

Hanging Baskets and Pot-Holders.—Among the various forms of these now in use is one of the most uncommon—that represented by the accompanying engraving. It consists of a wooden bowl, supported by narrow steel straps, strong, flexible, and elastic, and so contrived as to form a crown or balloon-shaped trellis above the bowl over which the plant is to be trained. Steel straps of this kind may be converted into pot-holders, by which a pot may be suspended at any time when it may be



Hanging Basket for Plants.

desirable to do so. Indeed, such trellises may be made useful in various ways, and they are capable of being made of many different shapes.—Q.

HEATING GREENHOUSES.

THE frequency of the above heading amongst "Queries" leads me to suppose that there are many amateurs like myself, who, possessing a glass structure and being ambitious of turning it to somewhat better account than merely keeping alive "bedding stuff," are in search of a means of heating it, which, while inexpensive and not requiring frequent attention, will enable them to preserve a healthy and steady temperature not falling below 45° at night. For their help, I ask permission to give my experience in such a search. It is proverbial that purchased experience is the most valuable; by this criterion the history I am about to give ought to be worth your readers' acceptance, though it will cost them nothing. Eight years ago I became the possessor of a greenhouse, with half-span roof and glass front, 20 feet long by 12 feet wide. Before my occupation it had been heated by a brick flue, but this was become old and ruinous, giving exit to much smoke and soot; and the fire-hole being out of doors, the keeping up the fire became a serious matter to an old man in winter weather. The whole system received its *coup de grace* at the hands of a groom, who superheated the flue, burning the wood-work and destroying all my first lot of plants. My next attempt was with a petroleum stove. This I found fairly reliable and not very expensive. The lamp required filling twice in the twenty-four hours, and consumed a gallon of oil in three days, but though the winter was mild I could never keep the temperature above 40° at night, and, either from that cause, or from the impure atmosphere, the plants became unhealthy, and many died. With so small a heating power it is impossible, except in very mild weather, to afford the plants any ventilation. My next venture was to utilise gas. A gentleman of my

acquaintance had invented a stove in which gas was burned in a cylinder while the air was heated by passing through tubes in the cylinder. This plan was tried with modifications for two winters, but was found both inefficient and expensive. The gas consumed cost 5s. per week, and the temperature could never be raised above 40°, while on cold nights many plants suffered from frost. I had by this time arrived at the conclusion that hot-water pipes afforded the only efficient means of heating, and having gas laid on, I had an apparatus fitted up which consisted of a copper gas-boiler and 44 feet of 4-inch iron piping. The cost of this arrangement and fitting it up amounted to nearly £20, but I was still as far from winter flowers as ever. During the hard winter of 1878 the full power of gas was turned on for more than three weeks together, yet the temperature could never be raised to 40°, and when the gas bill came in it was found that the cost of fuel was over 2s. a day, so the gas was dismissed for ever, and the hot-water pipes fitted to a coil boiler in a slow-combustion stove, and, when the mysteries of feeding and managing this stove had been mastered, my long search was over and my object gained. My stove was made by Messrs. Deard, of Harlow, and cost £3 15s. It is fitted with a hopper large enough to hold fuel for twelve hours' consumption, and burns about 1½ cwt. of gas coke (costing 1s.) per week. Its only drawback is that it now and then happens that the fuel becomes lodged in the hopper and so the fire goes out. This is prevented by care in breaking the coke, which should never be used in pieces larger than a hen's egg, and with as little dust as possible. Some mechanical appliance, however, like a spiral spring affixed to the cover, would, I think, be an improvement; with this apparatus, the temperature can be regulated with the utmost nicety. During the coldest weather of the last winter I could ensure a warmth of 45° at night, and, this being raised to 55° by day, allows scope for abundance of fresh air, and the plants continue fresh and healthy without syringing or special care of any kind. To show how much pleasure an amateur with little time and less skill can derive from such a house as I have described, I append a list of plants now in flower or ready to expand.

Chrysanthemums, Show and Japanese, Pelargoniums, Primulas, Cyclamens, Marguerites, Corn Marigolds, Browallia elata, Bouvardias, Echeverias, Abutilon, Begonias, Coronilla, Polygala, Boussingaultia baselloides, Hibbertia dentata, Fuchsia splendens, Eupatoriums, Epiphyllums, Heliotrope, Cuphea, Genista, Imantophyllum, Oncidium flexuosum, Cypripedium insigne, and Mignonette. After Christmas, the house will be kept gay with Azaleas and other hard wooded plants, Tea Roses and Dutch and Cape bulbs, until, with the returning sun-heat, the peeping of Alpine and other hardy favourites "long lost to sight to memory dear," transfers the paramount interest to the out-door garden, and the greenhouse "pales its ineffectual fires" before the coming summer.

I may add that, in my hands, the gas-coke has proved the best fuel. Any kind of caking coal is, of course, inadmissible. Anthracite coal, though beautifully clean, is expensive, and produces too fierce a heat; while house cinders, at least such as are produced by our west country coal, are apt, by running into clinkers, to choke the draught and give much trouble. P.

Trade Catalogues Received.—Messrs. Sutton and Son's (Reading) "Amateur's Guide in Horticulture"; B. S. Williams, Victoria Nurseries, Upper Holloway, London, N., "Flower, Vegetable, and Agricultural Seeds"; Messrs. Carter and Co., High Holborn, London, "Vade Mecum for 1881."

Curing Rabbit Skins.—Get a quart of boiling water; put in it as much alum as will absorb, allow it to cool, then plunge the skin in it for 24 hours. Let the skin get nearly dry, and stretch it as tightly as possible on a board with tacks or nails. Make a mixture of one-third salt and two-thirds pepper, and rub the skin well with it two or three times, and allow it to dry. When quite dry rub a very small quantity of oil in to make it pliant. The pepper should be the strongest obtainable, as it is that which cures it.—A CONSTANT SUBSCRIBER.

VEGETABLES.

THE JERUSALEM ARTICHOKE.

THIS is a tuberous-rooted species of Sunflower. Very little instruction is needed "how to grow" this vegetable, inasmuch as even Docks or Nettles are weak compared with its rampant vigour, and it will grow in any soil or any aspect; but for all this it is little appreciated. The Potato has furnished so many disappointments during the past twenty years or more, that we think in bad seasons this might be looked to as a substitute. To many it may appear inferior to the Potato in nutritive quality, but analysis has proved that it is so in but a slight degree; and when properly cooked and prepared a dish of Artichokes is very agreeable. When Potatoes, in addition to disease and bad quality, take to supertuberating, which they frequently do, a store of this hardy root becomes invaluable. Where the slightest knowledge of cookery exists

Jerusalem Artichoke in Bloom.

there can be no difficulty in serving it up in an agreeable manner; and it would be a boon to the poorer classes of cottage gardeners if this vegetable, and some simple but agreeable mode of serving it, were commonly known amongst them. As regards cultivation, it is often left alone in some bye-corner to take care of itself—for it is said that on account of the propensity of every little tuber, or small bit of root, to grow, it is not easy to get the land clear of it when once planted. If systematically cultivated, however, it is as easily and cleanly forked out of the soil, when ripe, as the Potato is, but the frost will not destroy any of the Artichoke tubers that may be left in the ground, or on its surface either, as it would Potatoes. The Jerusalem Artichoke is an extraordinary cropper, and free from any kind of disease, so that an abundant crop is certain with but little trouble in the preparation of the soil, and without the application of manure—which this Artichoke does not require. The only insect that attacks the Jerusalem Artichoke in summer is the wasp; when these are plentiful, in a hot, dry summer, they will attack the succulent stems of the Artichoke, for about a foot above ground, in such numbers that if left alone they will suck them dry, and kill them in a short time.

Culture.—Although, as before stated, the Artichoke will thrive in any kind of soil and in almost any situation, yet to grow it well, solid, and of a nice flavour, a good deep sandy loam, free from trees, is the best. This should be well trenched—that is, deeply—in winter, cast up into rough ridges, to sweeten and pulverise, and the bottom of each trench, as cleared, should be forked up with a strong fork and left loose; plant any time in the month of February; choose moderate-sized tubers, and place them at the bottom of every alternate ridge—that is, supposing the ridges to be 2 ft. apart—and place the tubers 2 ft. apart in each row; tumble the ridges down on them with a fork roughly, to be hoed or scarified amongst the plants as they appear above ground, keeping a loose, healthy earth surface amongst them by repeated scarifyings, &c. The tubers will soon grow on and take care of themselves; and if subjected to deep culture and cleanliness, the Artichoke will grow from 10 ft. to 16 ft. high, and produce immense crops, such as no other tuberous-rooted plant will in our climate. They are at their prime for culinary use from the middle of October till March.

They are generally boiled, but they are greatly improved in flavour and solidity by steaming them—a good handful of salt being placed in the water. They are also very good baked, or cut into slices and fried in the same way as Potatoes; and are also valuable for feeding poultry and pheasants. By long practice in their culture it has been found best to leave them in the ground where they grow till wanted; after being ripe, cut off the stalks a foot above ground, in order to know where the rows are, and to prevent the wind blowing away the protecting material, which in winter should be placed a few inches deep over the surface. This may consist of leaves, Fern, or light litter; and should have something placed on it to prevent it being blown away by the wind.

The tubers may be all cleanly trenched out in February, casting the covering refuse in the bottom of the trenches, the ground roughly levelled and planted again in the spaces between the previous rows. The Jerusalem Artichoke may be advantageously used as a screen in summer, to shut out unsightly objects, and if in positions where they can get plenty of sun and air, good tubers may be had from them.

When used for this purpose it is not necessary to make fresh plantations every year, but simply dig up the best of the tubers and allow the small ones to remain; if the soil be moderately rich, they may be grown in this way for years.

In open situations it will be often found necessary to afford some support to the plants, otherwise they are liable to be broken by the wind. Strong twine fastened to stout poles driven in the ground, answers as well as anything. Watering or mulching is not required except in very poor, shallow soils, when it may be applied with advantage. The botanical name of the Jerusalem Artichoke is Helianthus tuberosus. S.

Yield of Potatoes.—I planted 1 cwt. of Champion Potatoes last spring, and the exact yield was 25 cwt. of large eating Potatoes, and 7 cwt. of seed. The ground was newly broken up grass land. I have grown the American Rose over 1 lb. in weight, and I find them always wet in the early season, but if used later on they are like flour.—G. H. PRESTON.

Preserving Turnips in Winter.—Severe frost injures the tissues of almost all vegetables, and, with one or two exceptions, spoils their flavour and destroys their keeping properties when thawed again. When Turnips are grown in drills, and have room enough, it is a good plan to draw a little earth up over the roots with the hoe on each side the rows, but this need not be done till just before frost of a severe character is expected. This will, in a great measure, prevent that alternate freezing and thawing that does so much injury, as the

plants may be pulled up intact just before frosts sets in, and be laid in shallow trenches, just burying the bulbs. They will keep in good condition for a long time in that way. A few should, however, always be stored away in some cool place to be at hand in bad weather.

Early Peas under Glass.—Unheated glass structures, no matter what form they may have, are most efficient aids in forwarding early produce; and those who have abundance of such conveniences stand in a far better position than others whose means are limited. Peas of Tom Thumb, Blue Peter, Multum in Parvo, or any other of the dwarf growing kinds, sown now in boxes or pots, and placed under glass in a light position, will yield a good and certain crop earlier than could, under the most favourable circumstances, be obtained from an unprotected border. In the open border I find wire protectors to be great conservators of warmth, more so than anyone would believe who had not tested them side by side with rows unprotected, and they also, during the early stages of growth, which are generally the most critical, protect them from the depredations of sparrows.—E. H.

Good Onions.—One of the best cultivators of Onions I ever met with invariably grows them on the piece of ground which previously contained Celery. As the Celery is cleared away, the ground is trenched to the depth of 2 ft. or thereabouts, according to the depth and fertility of the soil; and his ground being a little stiff, he adopts the practice of throwing the rotten dung from the bottom of the trenches to the top. In dry, frosty weather, when the ground is frozen to the depth of 4 in. or 5 in., the frozen lumps are beaten to pieces with a mattock, and the surface of the ground left rough. About the last week in February or the first week in March, according as the weather proves dry and favourable, the ground is slightly forked over and the surface left as level as possible. In the course of a week, fowls' or pigeons' dung is thinly spread over the surface; and should the ground be damp, in addition to the dung, some charcoal dust is added, in order to make the ground work as freely as possible. The charcoal is also considered a fine manure for the Onion. Then the manure is forked in and the ground raked as level as possible. The seed is sown in drills 1 ft. apart, and they are not divided into beds, as it is thought to be a waste of ground if provision be made for paths. As soon as the plants are well through the ground, the hoe is used between the rows, and any weeds that may have put in appearance among the plants are removed by hand. As soon as it can be done, thinning out is proceeded with, and the plants are left from 4 in. to 5 in. apart in the rows; and hoeing and hand-weeding are continued as often as requisite. Grown in this way, fine symmetrical bulbs are formed, with but a very slight admixture of a coarse thick-necked type, for seed is saved only from the best-developed bulbs. When the bulbs are fully ripe, they are pulled up, and after lying on the ground for a few days they are brought into a shed to finish drying. In a wet season they are put into a frame or Vinery to dry, or into a Mushroom house where a little fire is kept on, in order to get them thoroughly dry, as the keeping of them entirely depends on this. A few are always selected for exhibition purposes. In dry weather these are helped with a little weak liquid manure, and as the necks begin to swell they are pinched by the pressure of the finger and thumb, so as to throw the strength of the plant into the formation of the bulb, and to secure that desired fineness of neck and firmness of bulb always so requisite in the eyes of good judges on the exhibition table, and also for Onions which are intended to be kept through the winter for use in spring.—R.

House and Window Gardening.

Dieffenbachia Picta.—All the Dieffenbachias are extremely handsome plants when young and well grown, but as they get old their stems become long and naked. The ease with which they may be propagated, however, renders this defect the less to be regretted; for, immediately they get "leggy," they should be decapitated, removing along with the crown an inch of bare stem. Insert this in a brisk bottom heat in a close, moist, and well-shaded frame within the plant stove, or under a hand-light in the same situation, and a new stocky plant, well furnished with foliage to the root, will be the result. Nor does this decapitation finish the task of the stem, for if it be kept in the pot it will soon emit shoots, those at the top being the most prominent, all of which can be taken off and treated as cuttings. By cutting the stem into as many pieces as there are joints, and laying them in sand kept moderately moist and in a warm temperature, they soon form plants. As window plants in summer, Dieffenbachias are very useful, their beautifully variegated leaves, together with their tropical appearance, rendering them great favourites. For house decoration it is not, however, advisable to have them in large pots, six-inch ones being sufficient, especially in cases in which they are placed within vases. When associated with Ferns, Alocasia metallica, and a few other plants, within a Wardian case furnished with suitable means of ventilation and good drainage, and situated in a warm room in a shady window, they form beautiful and lasting objects. A compost of equal parts turfy loam and fibrous peat, together with some well-decomposed manure and a little sand, suits the Dieffenbachia perfectly, but a little extra loam should be mixed with the soil for potting such plants of it as are destined for house decoration.

Dieffenbachia picta as a room plant.

A Good Table Plant.—Casuarina sumatrina is a very pretty plant when in a small state for table decoration, or the sprays of it may be used in many floral arrangements, and they are even more delicate in appearance than Fern fronds, and the soft green of its thread-like growth contrasts well with the deeper colour of its stem and older branches. For the adornment of cool conservatories this plant is well adapted, as it excels in appearance many plants grown for the effect their foliage produces, and which require a high temperature for their proper development.—J. L. M.

Convolvulus Mauritanicus as a Basket Plant.—This Convolvulus makes a beautiful basket plant at this season of the year when properly treated. Obtain established plants of it in six-inch pots, and in autumn place them in wire baskets filled with Moss. Thus situated, the slender branches droop gracefully over the edges of the baskets, and, if placed in a light position near the glass in a warm greenhouse or window, yield a profusion of pretty blue flowers all the winter.—S. C.

ROSES.

NATIONAL ROSE SOCIETY.

A SHORT account of the recently-held annual general meeting of the above society may interest those of your readers who grow and admire Roses.

There will be three shows in 1881, viz.:—July 2nd, at the Crystal Palace, Sydenham; July 14th, at the Botanical Gardens, Sheffield; and in September at the Botanical Gardens, Manchester, in connection with the Fruit Show. The schedules are most liberally drawn up, and give to all alike—nurserymen and amateurs, large and small—a fair chance of competing for the valuable prizes.

The Rev. Canon Hole, president of the society, will be asked to give a lecture on "Rose Culture" on the occasion of the provincial show at Sheffield.

The executive committee of the society will shortly compile a catalogue of the best Roses, giving date of introduction and raiser's name, together with full description as to colour, growth, &c. This will be a thoroughly reliable work, and it is thought that it may be sold for, say, 6d. per copy.

It was decided to accept the invitation from Bath to hold the provincial show there in 1882.

The funds of the society are in a satisfactory state, the balance in hand being £104. The secretaries of the society will be happy to give any further information to inquiring and sympathising friends, or I will do so.

Burton-on-Trent. WILLIAM WALTERS.

MARECHAL NIEL ROSES.

THOSE who are desirous of keeping up a good supply of cut Roses during the winter and spring months should get some standard Maréchal Niels, and also dwarf plants of that Rose, to grow on for another winter. Maréchal Niel, although one of the finest Roses for cutting purposes, is, nevertheless, not one of the most showy varieties for decoration in pots, inasmuch as the flowers hang down, and are hidden, to some extent, by the foliage. It is, therefore, best as a standard, but it is only in the form of cut flowers that I can recommend it. No Rose forces better than Maréchal Niel, and its flowers are always much admired when used for decorative purposes. Plants of it potted now will furnish a few flowers during the spring. When June comes those that have done flowering should all be shaken out of their pots and re-potted, so as to give them time to make growth for she following winter's forcing. I have cut fine flowers of this Rose at Christmas and on New Year's Day, but that was from plants the wood of which was strong and well-ripened—important points in the case of Roses that are forced early. In order to ripen the wood well, the plants should be placed in a warm, dry spot out-of-doors, watering very sparingly during the months of September and October, and replacing them under glass in November, or somewhere free from frost. When started for forcing they should be plunged in a bottom-heat of from 65° to 70°, giving top air for the first fortnight, so as to keep the tops of the plants cool, in order to check their breaking too quickly and feebly. If pushed on too fast we do not get a good break, and this Rose generally produces its blooms on the strong shoots. As the buds swell the heat should be increased from 55° to 60°

In Rose forcing, a strong top-heat should be avoided, as the flowers become drawn and sickly, and will often damp off before opening. Syringing, too, must be stopped, as water blackens the flowers and causes them to damp off. As soon as the blooming period is over, the plants should receive a slight pruning, and as soon as they begin to make a second growth—

about the latter end of May or beginning of June—they should be carefully examined and potted, removing most of the old soil; if any plant looks sickly, wash the roots clean, and then re-pot it in a compost consisting of half loam, one-fourth rotten cow-manure, one-fourth one-year-old leaf-soil, and plenty of sand and a small portion of soot, mixing all well together. The plants should then be plunged and grown in a humid atmosphere during the months of June, July, and August, watering occasionally with a little weak manure-water, and syringing night and morning till they have made their growth. Sickly standards, as well as dwarf Roses, should be treated in this way, and as soon as they have made or finished their growth they should be removed out-of-doors and set in some warm corner.

I have grown plants of Maréchal Niel with shoots from 10 ft. to 14 ft. in length in one season, and plants of it in 18 in. pots have produced from sixty to seventy blooms during the forcing season. Standards also flower well; they do not last more than three years in pots, but good strong plants of Maréchal Niel are so very cheap now that one does not mind the loss of a few plants. I find that Maréchal Niel on the Brier, and on its own roots, does best for pot culture as well as for other purposes. It grows very strongly on the Manetti stock, but two or three fine plants of it have gone off with me at the graft or bud. The Brier, in my opinion, is the best stock for it, if we wish to obtain its flowers in perfection. In selecting standards for pot culture, see that they are budded on good, clean, healthy-growing stocks, for if the stock be soft and sappy they will not succeed in pots. Rose-growers should always lay up in autumn some good rotten cow-manure, and keep it until the following season, so as to have plenty for potting purposes, as this material forms an important item in the soil for pot Roses if used in proper proportions. G.

Good Greenhouse Roses.—I have a house that is planted with Camellias, and Roses—principally Teas—are planted out amongst them; some of them are against the pillars that support the roof, and are trained along the rafters, partly for shade to the Camellias; others are trained to upright poles until they get above the Camellias, when they are allowed to spread just as they like. The blooms which they furnish for cutting are extremely useful, coming in, as they do, when the Camellias are failing. The first to bloom is the White Banksian, which flowers early in March, and continues to do so until the end of April. It is generally in full bloom at Easter, a season when white flowers are in great request; few white greenhouse climbers can equal it at that period. It covers a large roof space. All the pruning which it gets is done when the bloom is over; then nearly all the shoots are cut back to the main stem, an operation which causes it to push strong shoots, from 6 ft. to 10 ft. long; these are allowed to hang down as they like, and the following spring they are covered with bloom during their entire length. Maréchal Niel is trained to the rafters, and does well, coming in after the Banksian. Cheshunt Hybrid is a good dark-coloured, highly-scented Rose, and one which makes a good climber, but it is late in blooming, not coming in until the Maréchal is nearly over. Gloire de Dijon does well, but its colour is not so fine indoors as out; Catherine Mermet is one of the best; Adam Bell, Lyonnaise, Madame Sertor, Madame Willermoz, and Rubens all do well with me. I have tried several others, but for some reason or other they do not answer for greenhouse culture. Green fly does not trouble them much, perhaps because I use plenty of water at the roots and overhead, applying it in the latter case with the syringe. I have nearly always some buds fit for cutting.—N.

Umbrella-shaped Rose Trees.—We grow most of our dwarf Roses on the long-rod system, viz., cutting out the old wood at the winter pruning, and retaining the strongest annual growths, which are pegged down, at certain distances apart, with long stout pegs, cut from the refuse Pea sticks. On the summits of the Rose-banks, standards of free-growing kinds, such as Charles Lawson, are planted and pruned in a similar manner as the dwarfs, the points of the shoots being tied to pegs driven in a circle round the tree. By this means they form regular-shaped and beautiful heads, for the shoots break regularly into growth from every eye, and when in bloom form beautiful objects. —J. G.

THE SHRUBBERY.

Forming Shrubberies.—In the first formation of shrubberies a formal outline may be excusable, but the sooner the shrubs are permitted to grow over and through it, unless it be bounded by a path, the better. I have often thought the common practice of leaving a marginal border round masses of shrubs for flowers a mistaken one; too often, when such is the case, they present but a littery, rubbishy appearance. Can anything add to the beauty of a well-developed shrub springing direct from the fresh green turf? I think not; therefore let the Grass grow close up to the shrubs, without any bare soil intervening, and the different habits and styles of growth of the different

British Barberry (Berberis vulgaris).

shrubs in a well-arranged group will always give that variety of outline which is so pleasing. Of course, a little pruning may be necessary. Art may be permitted to mend Nature, so far as to stop or remove a robber shoot that is likely to destroy the balance of power in the plant. This is requisite in almost every form of tree or shrub growth. In the Grassy glades that intersect masses of shrubs, and which, when well and tastefully arranged, add so much to their picturesque appearance and beauty, groups of the more striking herbaceous plants may be used with good effect. Thus, a group of herbaceous Pæonies planted out in the Grass a few feet from its margin, in front of a mass of shrubs, has a far better effect than when growing in a crowded condition under or among the shrubs themselves. And the same idea could be worked out with many other plants, such as hardy Fuchsias, the autumn-flowering Anemones, and notably the Polygonums, such as Sieboldi and others. This appears to me to be the true way of bringing out the decorative force of any handsome or striking plant, but it must not be overdone. A single group of any suitable subject, well placed, would have a very striking effect; but to overtask the turf in this way would be ruinous. The great evil often noticed in the treatment of any given object is carrying the idea too far. It does not follow because a particular group in a certain position may look well and pleasing, that an increase in the number of such groups would have the same effect.—E. H.

Close-growing Plants for a Wall.—Those who wish to cover a wall with plants that require no training or nailing whatever will find the following to suit their purpose—viz.: Ivy—Hedera pulchella marginata (silver-leaved), Hedera aurea densa (golden), and Ampelopsis Veitchi. These three cover the surface of the wall evenly as they grow, and lie as close to the stone almost as if they were pasted on, and are at the same time very pretty. The Ivies show up brightly in their gold and silver variegation during winter and spring, and the Ampelopsis is successively bright green, dark chocolate, and crimson from May till Christmas, or later. If these be planted in a tolerably good soil they will grow rapidly and need no further attention. There are other Ivies nearly as good, but these are amongst the best, habit and colour of the foliage considered. As a berried plant the Cotoneaster Simmonsi may be added to the list. It also grows very flat and close to the wall, but wants just a nail and a shred here and there to keep the shoots in their places.—S.

Berberis vulgaris.—This is a British deciduous plant, growing to a height of 8 ft. or 10 ft., and bearing clusters of bright scarlet oblong berries. It forms a noble object on the margins of shrubberies or planted in groups on sloping banks and other conspicuous positions. Young plants are best, as old plants become "leggy" and unsightly. It will grow in any moist garden soil. The berries are often preserved in syrup or in salt for garnishing purposes during the winter, and they also make excellent refreshing preserves. Sometimes they are pickled in a green state. The fruit is sometimes seedless, and this is considered the best for preserving; but this character is not permanent, as young plants taken from those bearing seedless fruit will bear perfect fruit containing seeds.

Virginian Creeper scrambling over Shrubs.—The effect of allowing this beautiful creeper to ramble in this way is rich and striking. At a distance it looks as if the shrubs were clothed with glowing red fruit of enormous size. Looked at through the rays of the setting sun, nothing can be more rich and beautiful; the leaves seem aglow with crimson and gold, as if the rays of sunlight were passed through as well as reflected from them. As these plants seem to do little or no injury to the shrubs, they ought to be more frequently mixed among them and allowed to ramble at will for effect. They are far more beautiful thus than against walls. The colours may be equally or more brilliant on the walls, but the free growth and drooping branchlets give a grace and elegance unattainable on walls. Home plantations, as well as shrubberies, might often be draped with this charming plant. Its chief fault is the fugitive character of its brilliant colouring; hardly does it reach its best than the leaves begin to fall, but as a free, rambling plant, the Virginina Creeper is interesting and beautifnl at all stages of its growth. The ample size and verdant colour of its leaves, the drooping beauty of its shoots, and the interesting character of its clinging stems and tendrils, have been too much lost sight of while impatiently waiting for the fiery colour which heralds the fall of its leaves. —T. F.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

January 3.—Sowing Sweet Peas under the protection of a hedge; also in pots; potting autumn-struck Heliotropes; putting in a few Senecio cuttings in order to get up stock; also Vine eyes, Croton, Scutellaria, Petunia, and Calceolaria cuttings in heat (this being the best time for spring striking); putting Dahlias into heat for cuttings; planting standard Apple trees, Penny Royal, Fennel, Tarragon, Chives, and Lavender, and transplanting Lettuce; putting into slight heat a few Wallflowers weekly; also Kalmia latifolia; putting Salvia patens into heat for cuttings; placing Potatoes in loft very thinly to sprout for planting; looking over Pelargoniums and picking off damped leaves.

Jan. 4.—Digging ground for Onions; sowing some seeds of Viola cornuta, putting them into heat, and covering them with glass; also a box full of Red and White Celery; also Wood's Early Frame Radishes in pit, to come in middle of March; finishing potting Dendrobium nobile, and beginning with others, using very fibrous peat; planting Lilacs and Honeysuckle; planting Lavender and Wallflowers; putting a few Forget-me-nots in slight heat; laying turf wherever required; making leaf-bed for Carrots and Potatoes; pruning dwarf Apple trees.

Jan. 5.—Potting all Odontoglossums except a few nearly in flower, using Sphagnum and peat; also some Sweet Briers; putting in a good quantity of Carnation cuttings for blooming in October; also Fuchsias in heat for cuttings; planting some young Gooseberry trees; putting in Feverfew and Chrysanthemum cuttings.

Jan. 6.—Sowing seed of Salvia patens; potting Hollyhock cuttings; putting in cuttings of Achyranthes and of Tree Carnations; planting Hypericum calycinum under Oak trees, where they grow well; planting Rhubarb; shifting herbaceous Calceolarias into their flowering pots; covering up Celery with litter during frost only; giving Maréchal Niel Roses in pots a rich top-dressing; also Oranges; filling two-light frame with soil for Carrots and Radishes; cleaning Creepers in conservatory.

Jan. 7.—Sowing Syon House Cucumbers, and keeping them at 65° at night, 70° by day; giving Roses planted out in conservatory a top-dressing and watering; plants ready for house decoration: Lily of the Valley, Narcissus, Heliotropes, Hyacinths, Tulips, Callas, Sweet Briers, Deutzias, Scented-leaved and Scarlet Pelargoniums, and Mignonette.

Jan. 8.—Potting imported bulbs of Lilium auratum and placing them in a cold, shady house; also some yellow Calceolarias for early flowering; pricking off seedlings of Lobelia speciosa; planting Spiræa japonica, dividing the roots; also Daphne Cneorum and Schizostylis, and dividing them into small pieces; putting in another forcing of Rhubarb; looking over Apple and Onion stores.

Flower Garden.

Gladioli.—Bulbs of these should be looked over to see if any of them have suffered during the winter. If it is intended to purchase any new varieties they should now be obtained.

Hollyhocks.—It is necessary to propagate these early in the year, especially in northern districts, in order that the plants may have a chance to produce good spikes before the damp nights or rainy days of autumn prevent the flowers from opening well, or cause them to decay as soon as they are open. Plants of any scarce varieties may be placed in a little heat to start them into growth, and when the cuttings are long enough they may be taken off and started in a little bottom heat—just sufficient to feel warm to the hand. Cuttings put in late last year must be looked over, and any that may not yet have formed roots should also be placed in a little bottom heat. Those that are rooted may have the withered leaves picked off, and otherwise receive any attention which they may require. The old stools of ordinary sorts winter well in cold frames, if these are placed in a position well exposed to light and air; a damp situation must be avoided.

Glasshouses.

Orchids.—In cool Orchid houses carefully avoid using an excess of fire-heat, as nothing is more hurtful than a dry, arid atmosphere. Cool-house plants will require to be kept rather moister at the root at this season than any other Orchids. The temperature should not be allowed to fall below 45°, and it should not be pushed above 48° with fire-heat. Give abundance of air to this house whenever the outside thermometer stands above 48°, especially in calm weather.

Greenhouse and Stove Plants.—Any plants coming into flower should have a little extra encouragement at the root in order to enable them to develop fine heads of bloom. Established plants of Eucharis that have flowered late in autumn should be liberally fed, in order to recuperate their energies, when they will yield another crop of bloom as the days begin to lengthen. Keep the majority of the plants as near the light as possible, and maintain a temperature just sufficient to keep up a healthy circulation of the sap. Choice small plants, such as Sonerilas, Bertolonias, &c., will pass through the winter safest on a warm shelf near the glass, and should now be kept moderately dry at the root. Any plants infested with mealy bug or scale should be examined regularly every alternate day, with the view of thoroughly exterminating these pests. Plants of a woody character, such as Gardenias and Ixoras, on which mealy bug is troublesome, may have their main branches painted over with a weak mixture of tar and clay. This quickly makes short work of these insects, and has the additional advantage of sealing up their hiding-places on the branches. Hard-wooded plants must be kept well ventilated and carefully watered, giving sufficient of the latter at each watering to moisten the whole ball of earth equally throughout. Any plants affected with white scale should be thrown to the rubbish heap, as it is an almost hopeless task to clean them. Heaths are especially liable to suffer from mildew during damp weather, and any affected in that way should have a dressing of sulphur, blown off the palm of the hand amongst their leaves and stems.

Ferns.—Attention must be paid to the deciduous kinds of Ferns, which are apt to be neglected when divested of foliage. They should be kept moderately moist at the root all through the winter, otherwise much of their strength will be lost. The powdered varieties of Gymnogramma require a warm, dry atmosphere during the winter. Large plants of these should be frequently examined, and any parts damped off should be at once removed. Some of the more delicate varieties of Cheilanthes and Nothochlæna must be kept carefully watched, as, owing to their tomentose character, they are very liable to suffer from damp. Avoid giving Gleichenias too much heat; a temperature of from 45° to 50° will carry them safely through the winter; the only exception is G. dichotoma, which requires warmer treatment.

Fruit.

Vines.—A good Grape room should be dry, well ventilated, and heated with pipes from a boiler outside; but fire-heat in a room that is not subject to sudden fluctuations will only be needed when the atmosphere is damp or the temperature falls to 40°. The bottling system being now so well understood and appreciated, this portion of the routine may be dismissed with the statement that the most successful preservers of late Grapes have found the first week in January to be the best time for the final cutting. Immediately after the removal of the Grapes the Vines should be pruned and cleansed, in order that they may have a good three months' rest.

Strawberries.—The first week in January is a very good time for taking in the first batch of Strawberries in pots, provided they are in every way satisfactory, and unless this is the case it is useless to attempt forcing. Select the most promising in the smallest pots from one or more of the best kinds, wash the pots and examine the drainage before taking them indoors, and when the balls have become moderately dry, ram each plant, top-dress and place them in a light, airy situation, where they can be easily tended with water. Where Peach houses and Vineries have to do duty for a properly-appointed Strawberry house, it is much easier to lay down rules for the management of the plants than it is to carry them out; but one thing is certain, the Strawberry under glass must be started and carried on to the "setting" stage at a very low temperature, say from 40° to 45° at night with a rise of from 10° to 15° more by day, according to the state of the weather.

Vegetables.

As soon as the ground will admit of it, a border should be prepared for the earliest vegetables and salads, such as Peas, Carrots, Radishes, and Lettuces. The most sunny, sheltered, and driest situation in the garden should be selected for these early sowings, and they should have all the cultural aid that can be afforded, in order that they may the sooner supplant the crops of the same kinds now being forced. In this latter department, see that supplies do not run out from want of regular introduction of fresh roots. Seakale requires to be put in fortnightly, and Asparagus once in three weeks, in order to maintain a constant supply. For salads, a few Chicory and Dandelion roots should be planted in sand in any dark warm shed every week, and a few plants of Endive at a like interval will ensure a constant supply. When, through stress of weather, work runs short, hotbeds of leaves and stable litter can be made up for forcing Potatoes, Carrots, Turnips, Radishes, Lettuces, &c. Such forcing beds retain the heat longest when leaves preponderate—say two-thirds of leaves to one of litter. Frames may be placed on them as soon as they are formed, and on about 9 in. of light soil the seeds may be at once sown. If Potatoes are planted, the frames will require to be covered with mats to protect the tops from frost as soon as they peep out of the soil.

GLASSHOUSES AND FRAMES.

CONSERVATORY CLIMBERS.

Now that the short dull days of winter have arrived, it is high time to give attention to the thinning and regulating of all kinds of conservatory climbers, in order that the light and air which they obstruct may be allowed to have full play for the benefit of the plants beneath them. Much judgment and discretion, however, are necessary in doing this, for without a full knowledge of the habits of the different varieties and their mode of flowering, whether on the old or young wood, a good deal of mischief may be done. If we take the Bignonias, for instance, and remove the long dependent shoots made during the present year, we take away the bloom that would appear in the spring; and the same would happen in the case of the Lapagerias and others; but to prune out such from Passifloras, Tacsonias, and similar plants is a work of necessity, in order to allow room for fresh shoots to occupy their places. Those of the current season having so far served their purpose, at least two-thirds of them formed during the summer may be removed, leaving the remainder till fresh growth has made some progress, when they too should be cut away, except such as are likely to be required for laying in to fill vacant places.

This kind of treatment leaves just sufficient foliage to keep the roots slowly at work and the sap in circulation to feed the spurs and plump up the buds left near their base. The almost perpetual flowering character of Tacsonia exoniensis and T. Van Volxemi is such that it is impossible to cut away anything from them without sacrificing some bloom at the extreme tips of the pendulous shoots, and the only way to keep them in order is to be constantly regulating and encouraging the young ones, and gradually cutting out such as are getting too long or becoming exhausted. This will prevent undue crowding, and will allow their flowers to be seen to the best advantage. There is no way of growing these equal to having them in a lofty ridge, with just the main stems made secure, and the lateral branches allowed to depend straight down overhead, which is far more natural and effective than any kind of training, however well they may be carried out; indeed, these and Passifloras are only adapted to this mode of culture, and exceedingly graceful they are when well cared for and not allowed to get into a wild, entangled condition.

The great drawback to Tacsonias is their liability to scale, that often assails them to such a degree as to have the appearance of being splashed with minute spots of whitewash, and this kind of scale is, of all others, the most difficult to kill. The best remedy I have ever found is to paint the bark of their stems over with some Fowler's insecticide, mixed with clay, so as to make a thin wash similar to what Vines are usually dressed with, and this stifles them and keeps the plant free from attack for some time after. Paraffin used at the rate of a wineglassful to four gallons of water is a sure cure, and being so easily and quickly applied, as it may be by means of a syringe, is a great boon. Lapagerias, like Tacsonias, are also very subject to the same kind of insect, and likewise thrips, especially if they happen to be in houses where

the atmosphere is a little too dry, or other conditions not altogether favourable to their growth. Handwashing these is a difficult and tedious process, owing to the stiff and peculiar formation of the leaves, and here, therefore, the paraffin will be of rare service.

In regard to the general treatment of Lapagerias, the thing is to encourage as much young growth as possible, and the way to do this is to give an abundant supply of water from the beginning of April to the end of October, which will assist it through its flowering period as well. In Chili, its native habitat, it blooms during the rainy season, when the sky is dull and overcast, thus showing that it is fond of a good deal of moisture at that time; but when we look at the structure and immense substance of the flowers, they afford convincing proof that it must take abundant supplies to feed them. If well drained, and in a bed composed of rough fibry peat, as they should be, it is impossible during the summer months to give too much water, as they will nearly grow in it if it be not stagnant or remain too long in the soil to cause it to become sour and inert. The shoots of Lapagerias flowering only once they should be cut away when the blooms die off, unless it may be thought desirable to save seed. These come on pods of various lengths and sizes, and germinate readily when ripe, if sown in heat in sandy, peaty soil kept regularly moist.

Next to those already mentioned, I think Tecoma Jasminoides one of the most desirable of conservatory climbers, but to get it to flower freely it must have a very light house, with full exposure to the sun, in order to get the wood well ripened. Even with these advantages it is a shy bloomer when planted out where its roots can run unrestricted; and the way to produce the most satisfactory results is to confine it to a limited space, and keep it rather short of water during the early part of the autumn and winter. The habit of this, like the Bignonias, is to flower on the growth of the previous year, and the pruning, therefore, must be regulated accordingly.

Besides the general cleaning and regulating of all kinds of conservatory creepers, the present is the best time for adding to or renovating any old borders that may have become exhausted, or the soil in an unsuitable state for healthy root action, as, owing to the semi-dormant condition the plants are now in, they will bear more pulling about than at any other season. For the generality of them there is nothing better than good sods of fibry peat and loam chopped up rather coarse, and a liberal supply of sand added to keep it open and porous. If from 6 in. to 12 in. of this mixture is given, and a covering of the old soil laid over the top, it will result in a greatly increased state of health of the plants and a more floriferous habit.—D. S.

Filmy Ferns (Todeas).—The culture of these handsome Ferns is in many cases limited, on account of there not being in gardens suitable places in which to grow them. Any one, however, having a conservatory or greenhouse may easily cultivate them with little trouble or expense. Where beds exist in the conservatory, little semi-circular nooks may readily be formed in them by taking out some of the existing soil, and building all round with peat cut into convenient-sized turfs. A sheet of glass should be placed in front and one on the top, and the Ferns, which may either be grown in pots or pans, and placed on a little white gravel, or planted out, will, if kept moist, grow vigorously, and, in some cases, succeed even better than those for which more elaborate provision has been made. The idea was suggested by Todea Ferns similarly situated in the large conservatory in the Royal Botanic Gardens, Regent's Park; there, overhung with the fronds of graceful Palms and other plants, they succeed well, and have an interesting appearance. The walls of peat are rendered much more effective when covered with club mosses, small-growing Ferns, Fittonias, Ficus minima, and similar plants.—S.

Cestrum aurantiacum.—For training to pillars or rafters this fine climber is unequalled amongst autumn-flowering greenhouse plants, and it is, moreover, a plant requiring the simplest culture. It should be planted in a bed of rich soil, and be cut hard back in spring. Thus treated it will not fail to produce every autumn a profusion of rich golden blossoms in long, drooping terminal branches, which contrast finely with the bold deep green foliage. Though it is a native of Guatemala, it has proved itself capable of withstanding the winter, with only the protection of a wall.—W.

An Ornamental Grass (Agrostis pulchella).—This very pretty ornamental Grass has been so useful to us for mixing with cut flowers for vase and room decoration, and so much admired when used in this way, that I have much confidence in recommending it to all who grow Ferns and other choice plants for producing fronds and sprays of green for this purpose. It is an annual, grows from 9 in. to 1 ft. high, and when used as above it gives elegance to flowers so arranged, such as is rarely met with. Sown annually at the end of May in small clumps on the herbaceous or flower border, and covered slightly with fine soil, it will grow freely, and be very acceptable for cutting at a time when the beauty of many things grown outside is fading. It requires no more care while growing than keeping free from weeds, and a few small stakes and matting placing round the clumps to prevent the wind from blowing it to the ground. We have grown it for several years very successfully as described above; but the present year, instead of sowing it outside, we sowed a few 6-in pots. with it, placed them in a little heat until the seedlings were up, and then removed them to a cold frame, intending finally to plant it out without breaking the balls of earth; however, our borders were so full of other gems we could not find room in which to plant it, so we placed the pots on ashes for a few

Ornamental Grass (Agrostis pulchella) for pots or borders.

weeks in the summer, and took them into a cold greenhouse at the end of September, since which time from a limited number of pots we have been cutting regularly, and shall be able to continue doing so for some weeks to come. It will keep well in any part of the greenhouse where it can have some degree of light, and the soil in which it is growing kept moist. We cut the finest spikes first with a pair of narrow-pointed scissors; this allows the lesser spikes to develop as large as those first cut. All who have seen it growing in pots think it very pretty, and have wished to know the name of it that they might grow it for themselves.—T. J.

Anderson's Speedwell (Veronica Andersoni).—This is one of the best of the larger-growing Speedwells for winter flowering in pots, and its deep blue blossoms are valuable in a cut state, or on the plant they supply a colour in the conservatory by no means plentiful. In mild winters it sometimes lives out of doors near London. Cuttings struck in spring and grown on into 6 in. pots, or planted out in June in good soil, and lifted and potted in October, make bushy plants for Christmas.

Pompone Chrysanthemums. — The neat little plants of this section, to be found in the London markets in autumn, are the produce of cuttings inserted in cold pits or frames, or under hand-lights in June. These cuttings are obtained from old plants grown in some stray corner for the purpose. They are planted thickly in sandy soil, well watered, and kept shaded until rooted, when air, light, and sun are freely admitted to them. When well established, they are transplanted in an open border of sandy soil 18 in. apart. Stopping the shoots is practised, sometimes twice, the last time being just before they show bloom-buds. They then make dwarf bushy plants, which are lifted and potted in 5-in. or 6-in. pots, as soon as the buds are set, and placed in a half-shady situation until frost appears, when they are taken under cover until they come into flower.—S.

Hyacinths and Tulips for Winter-flowering.—These, as well as Narcissi and other bulbs, are now being forced for market by thousands, one grower alone using as many as 80,000 bulbs yearly. They are potted in 6in. pots as soon as received from Holland in autumn, and are placed in square beds out of doors, and thickly covered with Cocoa-nut fibre. This, being light, can easily be removed in order to select the most forward bulbs from time to time for placing in heat. In order to discover which are ready for forcing, they are turned out, and if well-rooted are taken indoors, plunged in a gentle bottom heat, and kept dark until their flower heads show themselves; light being afterwards gradually admitted to them until they will bear full exposure. The first batch of Hyacinths and Tulips is sent to market the day before Christmas, if possible, and a succession is henceforward kept up until they come into flower naturally out-of-doors. Roman Hyacinths are also grown in considerable quantities. They bear rapid forcing, and come into flower from October to Christmas, when flowers are scarcest. They are forced, as a rule, in shallow boxes, and potted four or five bulbs in a 6in. pot just before they come into blossom. They are also largely used in baskets and vases, but their chief value is for making bouquets, as, on account of their sweet-scented pure white pips, they can be used for such purposes, with the certainty that they will be appreciated.—S.

FRUIT.

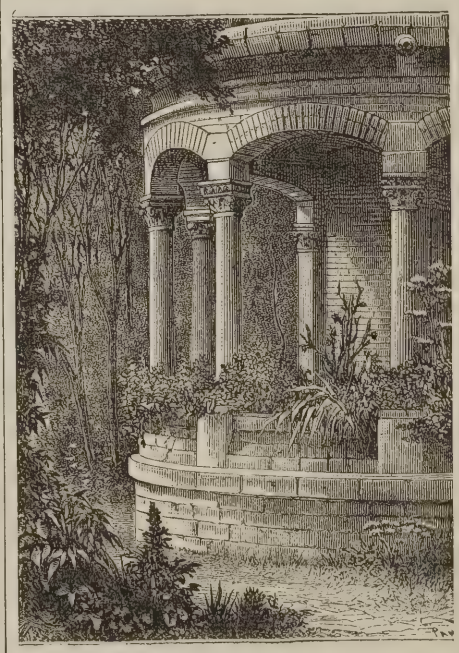
Winter Covering Fig Trees.—Although the wood of Fig trees will withstand any ordinary frost without injury, it is best to be prepared against exceptionally severe weather, as I find trees of several years' standing to be much more fruitful than young, fresh-planted ones, which even in poor soil will produce shoots of too luxuriant growth to either withstand frost or produce much fruit; and, as the labour involved in protecting is trivial compared with the crops which a few good trees may be relied on to yield, I find it best in our uncertain climate to cover the trees about the first week in December. Our trees, which are fan-trained, are unfastened from the wall, and the wood is laid in a bundle at its base, where it is easily covered with any available material. We use Reeds for the purpose, from their being plentiful on the marsh lands here, and therefore of little value; they are cut and stored in autumn, and they will last good for several seasons. We cover the bundles of shoots sufficiently thick to exclude light, as that, acting on the frozen wood, is probably more injurious than frost. As soon as all danger from severe frost is over, the covering is removed, when any pruning required is done, and the wood is again fastened in its former position. Short-jointed, well-ripened shoots will almost invariably produce a crop, even when other fruit crops fail. The longevity of Fig trees is proverbial; the finest and most certain-cropping tree we have is probably over 100 years old, and is annually laden with hundreds of fine fruit.—H.

Preserving Grapes in Bottles of Water.—I have often thought that if those who recommend this mode of keeping Grapes throughout the winter would not give such elaborate instructions about the "Grape-room," more people would be induced to try the system. We have no finely fitted-up Grape-room, and yet I keep Grapes, even tender-skinned ones, successfully in bottles of water. The place in which we keep them is an ordinary room, round the walls of which are several shelves about 9 in. wide, and to each of these is fixed an upright board about the same width. Along the top, every 4 in. apart, is cut a notch 1 in. wide and 1 in. deep. Quart wine bottles are set along the shelves as closely as they can be put; each bottle is filled with water, into which are

put a few pieces of charcoal, and laid in a slanting position, with the necks in the notches just alluded to. This is a simple way of erecting a Grape stand, but it answers admirably. Each bunch of Grapes is cut off the Vine with about 6 in. of wood attached to it; the end of this wood is inserted into the neck of the bottle so as to be about 2 in. in the water, and the bunch hangs over the front of the upright board. The mouths of the bottles are not stopped, and the water is never changed, but filled up as it evaporates; no fire-heat is used in the room, but daylight is admitted as in the case of an ordinary dwelling. During damp, sunless days, the windows are never opened, but at other times air is freely admitted. We have had some score of bunches of Black Hamburghs cut and bottled in this manner since the beginning of October, and not more than two berries in each have decayed during that time, all being plump and fresh, while some of the bunches left in the Vinery have lost half of their berries, and others are shrivelling; so that the advantages of bottling are very apparent. I may state that the room is kept at no given heat, but fluctuates with the outside temperature; frost must, however, be excluded.—C.

Renovating Unfruitful Vines.—It is a very common occurrence to meet with amateurs whose Vines are a source of continual annoyance to them, going on year after year bearing but very little fruit, and what they do produce of an inferior description, through shanking, a condition which may generally be traced to an unsatisfactory state of the roots, which have got too low down in damp, ungenial soil, or where there is an accumulation of stagnant moisture. In all such cases, instead of dallying with them and looking season after season for more satisfactory results, that are not realised, I should recommend the roots at once to he lifted, and a new preparation made; in the first place there should be sufficient drainage, which may consist of 8 in. or 10 in. in thickness of broken refuse—bricks, burnt clay, clinkers, stones, or anything of a similar nature that is most easily obtained; on this lay a bed of good ordinary new soil, of not a too light sandy character, and, if very heavy and retentive, add a sufficient quantity of sand, lime-rubbish, or burnt clay, to make it sufficiently porous without being too open. It will also be an advantage to add to the soil ½ in. or 1 in. of crushed bones at the rate of about a bushel to every three or four superficial yards of the border. In the absence of these, if the soil be not naturally rich, a moderate quantity of good rotten manure should be added. The work should be commenced by removing the soil at the furthest part of the existing border away from the front of the house they occupy, using forks for the purpose, so as not to mutilate the roots, which must be carefully dealt with and taken up as entire as the nature of the operation will permit; all the existing outside border ought to be removed, if there be an inside border as well, and if it be ascertained on examination that there is a fair amount of roots in the inside; if the border be all outside, about 3 ft. or 4 ft. of the portion nearest where the Vines are planted should be left undisturbed, as if the whole length of root were lifted so late in the season as this most likely they would not bear much next year, and lifting the lower extremities of the roots and placing them sufficiently near the surface in new soil will generally be found effectual. Before replacing the roots, they may be shortened to about half the length that has been taken up, spreading them out evenly, and bringing them to within 8 in. or 9 in. of the surface; when the work has been completed, on the top of all, 8 in. or 10 in. of litter should be laid, so as to throw off heavy rains and keep out frost, as if the soil were congealed down as low as the roots the latter would be seriously injured. If there happens to be any spare frame lights, wooden shutters, or, failing these, an old oil sheet, or anything that will ward off excessive rain, it will be a still further advantage. Many people are deterred from interfering with the roots of unfruitful Vines, and remaking the bed in which they are grown, under the impression that it involves a serious amount of cost and labour; yet such is by no means the case, as there is little difficulty in the matter when new soil can be had without considerable expense. I have found that the best time for lifting Vines is at the close of August or beginning of September, whilst the leaves are fresh and green; but in most cases with amateurs who do not start them early, they are bearing more or less of a crop either ripe or approaching maturity at that time; consequently the work has to be deferred until later on, often till the present season. Vines that are thus lifted should by no means be hurried in the spring, but left to come on with little, if any, excitement beyond that resulting from solar heat.—T. S.

Flowers on Walls.—There is a way of growing flowers on walls in various countries which deserves more attention than it has received with us. It consists of leaving the upper portion of a terrace or wall hollow, and using this for flowers. The crest of the wall is, in fact, a narrow flower border; but though narrow, with a space for 2 ft. or 3 ft. of soil from 1 ft. to 3 ft. through, thus giving ample root room for the production of a vigorous and graceful vegetation. The architect or builder can easily arrange for such wall-vases. The accompanying illustration shows the effects obtained in the slender wall of a small garden pavilion. We have often seen very charming effects produced in this way on the Continent, even in poor houses where little evidence of



Gardening on Walls.

other beauty was to be seen. By adopting the principle of variety instead of repetition in such cases, a beautiful garden of flowers might be grown on the crest of many a barren wall near, or part of, a town house. Hardy plants of a permanent character should always be chosen for such positions, and those with graceful foliage should have the preference. A top dressing of rich soil could be given yearly, and when well established, such plants as the smaller Yuccas, Acanthuses, &c., would make a charming effect.

Dicentra (Dielytra) **formosa.**—This has formed with me an excellent border plant during summer and autumn. It resembles the kind known as D. eximia, but is of a stronger and hardier habit of growth. It also flowers more freely, and its blossoms are larger and of a brighter rose colour. It forms an excellent band to a shrubbery, or isolated clumps of it in raised positions produce a good effect, or, backed up by a row of variegated Cornus, it has a fine appearance. In rich, deep soil it grows with great freedom, and flowers successively for several months. Its blooms are useful among cut flowers, and its leaves may be used in like manner as a substitute for Ferns.

Michaelmas Daisies.—Among the many kinds of these ornamental autumn-flowering Asters, few are more graceful in habit than A. pendulus and A. ericoides. Isolated in light, open places, these two kinds have been very attractive. The flowers are, of course, much inferior to such kinds as A. Amellus, but this loss is amply substituted by the profusion in which they are produced, as well as their longevity.

SELECTING AND PLANTING FLOWERS.

In selecting hardy plants for a small garden, preference should be given to those which have been improved into florists' flowers, as by using them a varied display of colour can be obtained with varieties of the same plant, which lessens the difficulties of soil and treatment.

A splendid and varied succession of flowers may be obtained from plants of the florists' classes without going in for the expense and trouble necessary to bring them up to exhibition mark, and in several kinds there are hardy, free-flowering varieties, quite as showy for gardens or cutting, and more suitable for ordinary border cultivation. Every garden of hardy plants should contain a selection, however small, of each of the following kinds:—

Flowering from March to June:—Early Tulips, Parrot Tulips, Alpine Auriculas, Border Auriculas, Border Polyanthus, Pansies, show and fancy, Ranunculus Turban and Turkish, Anemones coronaria, and stellata, single and double late or show Tulips, Pyrethrums, flowering in May and again in autumn.

Summer Flowering:—Pinks, show and fancy, Carnations, show and border, Antirrhinums in variety.

Summer and Autumn Flowering:—Pentstemons in variety, Chrysanthemum indicum in variety, Phloxes, early and late, in variety, Chrysanthemums, Pompones in variety. The varieties of each of these kinds vary from forty or fifty to several hundreds.

Of other hardy plants, the Iris and the Lily should on no account be omitted. The common German Iris has sported into many varieties quite worthy of being associated with the choicest florists' flowers, and the English and Spanish Iris are quite equal to florists' flowers in beauty and variety. Of the Lilies, the Common White, L. auratum, L. lancifolium rubrum, L. chalcedonicum, and L. tigrinum and its varieties, are neither expensive nor difficult to grow.

Of other herbaceous plants the following are the very best, and should give in ordinary seasons a succession of flowers extending over the greater part of the year. As florists' and half-hardy flowers and annuals will keep the summer garden gay, the selection contains a large proportion of spring and autumn flowering plants:—Christmas Roses (giant and common), Scilla sibirica, Anemone appenina, Anemone pulsatilla, Anemone nemorosa and its double rose-coloured variety, Anemone sylvestris, Hepaticas in variety, Anthericum Liliastrum, Aquilegia vulgaris in variety, Aquilegia chrysantha, Aquilegia cærulea, Aquilegia cærulea hybrida (Veitchii), Dog's-tooth Violets in variety, American Cowslips in variety, Polyanthus Narcissus in variety, Narcissus Trumpet, major and minor and Orange Phœnix, Paper-white Narcissus, Narcissus poeticus, Narcissus Jonquilla, Crown Imperials, Triteleia uniflora, Primroses (single and double) in variety, Primula cortusoides amœna in variety, Delphiniums in variety, Calandrina umbellata, Phlox verna, Phlox setacea in variety, Brodeia coccinea, Campanula Hendersonii, Campanulas in variety, Dielytra spectabilis, Spiræa japonica, Spiræa filipendula flora plena, Spiræa palmata, Lychnis Haageana, Lychnis chalcedonica flora plena, Œnotheras in variety, Omphalodes verna, Trollius europæus in variety, Ranunculus aconitifolius plenus, Potentillas in variety, Stobæa purpurea, Statice incana, Statice latifolia, Vinca major, Vinca minor, Anemone japonica hybrida, A. Honorine Jobert, and Senecio pulcher.

Nearly the whole of the above list of plants have been described in detail in the pages of GARDENING, so that only two require comment—namely, Spiræa japonica and Dielytra spectabilis. These being usually grown as greenhouse plants, have come to be regarded as tender, whereas the first is quite hardy, and the second nearly so. Spiræa japonica should be procured as strong clumps in the autumn, and planted where it is sheltered from the sun in the heat of the day in summer. It must never

be allowed to want water while it is growing, or it will suffer seriously. Out of doors the foliage is much darker in colour than when grown indoors. Dielytra spectabilis may be seen growing in two small front plots at Hadley, near Barnet, facing east, and exposed to the full sweep of the north-east wind, the ground falling rapidly to the eastward. The position is as high as Hampstead and Highgate; the soil, a rich loam resting on gravel. Last May both clumps were in flower, and one was between four and five feet across, so that there can be no question of its hardiness in dry, well-drained soils, in positions where it escapes damp frosts. In a bed by itself on a sunny lawn its beauty would be seen to advantage. The clumps above-mentioned spread their drooping leaves and flowers equally on every side, which they could not do if crowded by other plants.

Planting.—Herbaceous plants should be planted in September, but many of them can be more readily procured in spring. They do not in that case flower well the first year. The ground should be a rich, deep, well-drained loam, and should be well dug two spits deep, and liberally manured with old, well-rotted manure. This should be well mixed with the soil. Planted in such a soil, nearly all the plants above-named will require no further attention for several years, with the exception of such bulbs as Tulips, which require lifting and drying. When the clumps show signs of deteriorating they should be lifted and divided, and fresh soil and manure added; but the soil should never be dug all over, as that is only destroying the roots of the plants; neither should leaves of trees which fall on the beds be swept up: they are the natural food of plants, and will soon disappear. With a well-planted herbaceous garden the services of the jobbing gardener may be dispensed with, except to cut the grass, roll the walks, nail up climbers, and remove weeds. A mulch of well-rotted dung should be laid amongst the roots of the plants in winter, and pricked in with a fork before the plants start growing in the spring, and the result of this simple culture will be a far more enjoyable and ever-varying garden than any bedding plants can possibly produce. J. D.

RENOVATING BEDS OF LILY OF THE VALLEY AND FORMING NEW ONES.

THE Lily of the Valley is a flower which everyone admires, but which few grow as it deserves to be grown. The plants are often allowed to get overrun with weeds, and consequently flower very sparingly. They should be kept quite free from weeds, and the soil between the roots should be frequently stirred, especially after heavy rains. Great attention is required after the flowering period, as it is then they begin to root and prepare for the next flowering season. They ought never to be allowed to get too dry, from the time they have done flowering until August, and should receive a watering of liquid cow manure once a week. The roots should be taken up and replanted at least every four years. In doing this, as well as forming new beds, the ground must be deeply trenched and thoroughly cleaned. In whatever shape or form the beds are the roots should be planted in drills about 3 in. to 4 in. apart each way, but so that the crowns stand above ground. Then just cover the crowns with old, well-decomposed leaf mould. Planting may be done from the end of October till the end of March. Although the Lily of the Valley delights in a shady situation, it will grow quite as well in sunny places, but the blooms will not last quite so long. The bare places under trees, shrubs, &c., might soon be improved by planting Lily of the Valley, which, with its delicate and fragrant flowers and lovely green foliage, will soon repay the little trouble bestowed upon it. T. J. D.

The Irish Heath (Menziesia polifolia var).—The flowers of the white varieties of this native plant may be classed amongst the most lovely of all delicate blossoms, and when seen upon the plants, or when cut for use as domestic or personal ornaments, they are able to compete successfully with even the most select of tropical flowers. During the past few years, blooms of the white varieties have been welcomed by Covent Garden florists, who make excellent use of them in the arrangement of bouquets; but it is as seen on the dark-leaved little bushes themselves that the spires of snowy bells are most attractive, and a rood or so of these plants 18 in. or 2 ft. apart would be a very serviceable addition to any garden where cut flowers of a choice character are desired, or a few plants might be used as a fringe to beds of Rhododendrons and other American plants. Although a peat soil is eminently suitable for these Heaths, nevertheless it is by no means an absolute necessity, as a good fibrous loam meets the requirements nearly as well, and, like most other plants, they evince a preference for pure fresh air. The type (No. 1 in the annexed illustration, the upper figure to the left), as found so abundantly in some parts of the west of Ireland, bears bells of a ruby-purple colour; (No. 2) M. polifolia var. alba, has snowy-white bells; then of this there is a large and more inflated form (No. 3) known as alba major or globosa, and the variety (No. 4) named M. polifolia bicolor is perhaps the most singular of all in its changing variations, which range from pure white to deep purple, through all the intermediate tints of blush-white and pink, while some of the bells are distinctly striped with purple on a white or blush-coloured ground. All these variations may occasionally be found on the same flower-spike, as is shown in the engraving in the upper right-hand figure. —F. W. B.

Varieties of Irish Heath (Menziesia polifolia.)

RIDGING UP SOIL IN WINTER.

I AGREE with all that Mr. Cornhill has said (p. 486) respecting the ridging of ground in winter. Our soil here is of a stiff, retentive nature in winter, but bakes and burns in summer; and if it be stiff and lumpy in the spring, or run into a state akin to the consistency of clay with excessive moisture, it becomes almost impossible to crop it fitly or to reduce it to a pulverised condition. Ridging will do good if it be done whilst the soil is fairly dry in the autumn; but if the operation be left until it has become saturated with wet, then it will turn up in huge lumps, and in lumps it will remain unless severe frosts pulverise it. I would often like to have my uncropped ground neatly dug or forked over in the autumn, or during open weather in winter, but if I did have it so worked and a week or two of rainy weather succeeded, it would then look very much as if it had been rolled, and would run together in such a way as to make moving it in the spring heart-breaking labour. Where it cannot be ridged and it is intended to dress it with stable manure in the spring, it is far the wisest plan, even at the risk of being thought untidy, to leave it untouched, weeds and all, for the winter, and let the worms do the work of aërating, which they will perform much more effectually than human labour can. When it is intended to grow Potatoes—our staple crop here—with patent manures, I like to turn up the soil in ridges 2½ ft. to 3 ft. in width, and to allow it to remain rough and unkempt for the winter; then in the spring, when the soil has become fairly dry, have the furrows forked over, draw shallow drills with a hoe, plant the tubers, dress with the manure, and fork down the pulverised soil from the sides of the ridges to cover the seed. The remainder of the ridge can then be forked down at leisure either before or after the Potato plants appear. Planting of all kinds of hardy flowers, such as Primroses, Polyanthuses, Pansies, &c., that should be done in the autumn, and in some cases must be, let the result be what it may, is, nevertheless, best done in the spring, as the rains of winter cause the particles of the soil to run tightly together, the roots are fixed as in a vice, and in the heat of summer the soil is baked so hard, that it is almost impossible to get it clean and usable. It is an undoubted axiom that the wetter the soil in winter the more will it bake in the summer; whilst a dry soil in winter, if it be of average depth, will be the coolest in summer. The more the soil is pulverised, the more the surface is disturbed and made fine, the more retentive is it ot moisture; and, except when the winter has been severe and the frost has thoroughly entered the soil, the highest condition of pulverisation is found when the worms have had undisturbed action, and the ground has lain untouched till March, or until dry weather prevails. Recent winters have rendered the ground more difficult to work in the spring than was formerly the case. Then several weeks of severe frost did a large amount of good; now, mild winters and heavy rainfalls

keep the weeds growing, render the ground close and heavy, and leave slugs, snails, and other pests in undisputed sway. I heartily recommend all who have stiff clayey soils to cultivate to use some discretion about moving them in the autumn or winter, lest the labour they bestow on them may do more harm than good.

A.

POLYANTHUSES AND AURICULAS.

ALTHOUGH the bedding-out system, as it is termed, has many crimes against hardy plants to answer for, I do not think the default in the cultivation of choice Polyanthuses and Auriculas can be laid at its door. It is notorious that these once-favoured florists' flowers never were grown by gardeners, or those of the horticultural fraternity, who have been at any time bitten with the "bedding-out" mania. With the exception of the few trade growers, at all times but a few, who have from time to time cultivated them, almost all other growers have been amateurs—that is, persons who found in some other profession or trade than horticulture a livelihood, and grew these particular plants as a hobby, or as a healthy and interesting means of recreation. The real hardy plants that have suffered from the practice of "bedding-out" have been all those fine border plants that will grow almost anywhere outdoors under ordinary cultivation. As a result, thousands of gardeners have grown up who had no more knowledge of the great mass of hardy plants than the plants had of them. Choice or florists' kinds of the Polyanthus and Auricula could never have been brought into that category; they are not border plants, and could not be grown as such. Just as the monks of the Middle Ages, in their secluded monasteries, kept alive in an ignorant and careless world a taste and love for intellectual knowledge and culture, so also did the few descendants of the old florists during the interregnum, through which I happily believe we have passed, keep alive the interest in Polyanthuses and Auriculas, and now we find that limited interest is fast increasing, so that there is hope in a few years these ancient florists' flowers will be more widely grown than ever. Why there should have been a decline in their cultivation as exhibition plants it is no more possible to explain than is the almost entire collapse of Tulips, Ranunculus, Anemones, and many other equally good things which, a few years ago, were extensively used as show plants.

It is, perhaps, but natural that new generations should have other tastes, but if it is possible to lead some of the younger lovers of flowers back into the ways of their forefathers, and to develope a fondness for some of the old loves, really good service to hard plants will be done. I am pleased to find a firm like that of the Messrs. Clibran can offer plants of many of the fine old kinds, although I fear that the sorts offered so low as 9d. each would have little affinity to the fine old kinds that, because of their rarity, are necessarily so dear. I have before me now a trade list which shows even such inferior kinds as Black Prince and Napoleon are quoted at 1s. 6d. each, whilst Cheshire Favourite is 2s. 6d., Exile and Formosa 3s. 6d., and Lancer and George IV. 7s. 6d. each. It may be taken for granted that these are the lowest prices at which they can be offered, and yet it is found almost impossible to get good strong plants sufficiently fast to supply requirements. A Lancashire trade grower of good reputation wrote the other day that he could not issue a list this year, as many of his kinds had largely suffered. It is such ailments and difficulties in culture and increasing a stock of these choice things which keeps them so dear. It may be assumed that the trade growers would be only too pleased to sell them cheaper if they could. A seedling new kind would, perhaps, take ten years to make a few dozens of plants, even if all possible mishaps were avoided. Old kinds increase much less rapidly than this, and some it is difficult to keep alive at all. These remarks apply almost with equal force to Alpine Auriculas, but good kinds of these may be had at about 20s. per dozen if not too choice, but of course new kinds are more costly. No doubt those who may be induced to embark in the cultivation of these choice flowers (and may they be many) will soon learn to realise the high value of their plant pets.

A. D.

ANSWERS TO QUERIES.

3869.—**Raising Seeds.**—Keep the seeds in a dry place till March, then sow in 6-in. pots in light sandy soil—say two-thirds peat or leaf-mould and one-third loam, with plenty of sand to keep it open. Press the soil in tolerably firm. If the seeds are soaked in lukewarm water for twenty-four hours before sowing they will germinate quicker and better. Do not cover them too deep, and place a square of glass over the top of each pot. They will grow in the greenhouse without bottom-heat, although doubtful seeds do better with it. Keep them just moist only till they grow.—E. H.

3880.—**Culture of Lilium Giganteum and L. Washingtonianum.**—In the case of L. giganteum some little patience on the part of the grower is necessary, for this Lily requires four, and sometimes five, seasons' growth before it comes into a flowering state. The proper time for shifting it is just as the foliage dies off, and a nice fine, mellow compound of fibrous loam should be employed, adding to it some leaf-mould and a little well-rotted manure, for this is about the only species that is really benefited by the addition of manure to the soil. It is, indeed, a greedy feeder, and should have free supplies of liquid manure when in full growth. During the winter keep the soil moist, and keep the bulb in a cold frame or greenhouse, or even outhouse will do, for it is hardy enough; but when in a box is better for some protection. It also enjoys the shelter of a glass roof during the spring months, but if this accommodation cannot be afforded it may be placed in a sheltered situation in the open air, where it may remain until the blooms are showing, when the protection of a glass roof will again be desirable. After flowering, the old bulb dies away, but young offshoots are generally formed, which may be taken off, and will flower in their turn at their appointed time. With respect to open-air culture, there is no great difficulty, as, even when the situation is cold, the safety of the bulb may be ensured by a coat of ashes or cocoa fibre. The best place for this Lily is amongst Rhododendrons, or shrubs of early growth, where a certain amount of shelter is afforded not only in the winter but also in the spring, when the young, tender foliage appears above ground; and the best soil is that which contains a considerable amount of organic matter and a fair proportion of sand. Thus a compound of sandy peat loam and leaf-mould in equal proportions will suit it well. One reason why many fail with this Lily is that the foliage gets injured by our late spring frosts, and when this is the case the bulb does not much increase in bulk that summer. Snails are also extremely partial to the succulent foliage of this plant, and it is oftentimes a matter of considerable difficulty to protect it from their ravages. A good coating of soot around the bulb will keep them from passing over the soil on to the plants, and when they make a bridge of other plants to cross on to it, the leaves may be finely sprinkled with soot. Generally speaking these pests appear most in spring, and if watched for at night for a time they may be killed off before the summer arrives. For the treatment of Washingtonianum we refer you to p. 493, answer 3755.—G. C. B.

3884.—**Draining a Garden.**—First dig a hole or two in the garden, say 3 ft. deep, leaving them open, and see how high the water rises. If it attains the height of the pond, digging a blind well will be of no use, and it will be better to rest content with the 22 in. in depth that will utilise the pond as an outfall. Advantage should be taken of every opportunity of raising the surface that occurs in after years.—E. H.

3922 and 3931.—**Garden Walks.**—"S." and "Venetian Red" would, I think, find concrete answer their purpose. Burnt clay, slag, or sandstone, finely broken, or gravel will answer; the materials should be from the size of eggs to peas; a little of the dust will not spoil it, however. Six parts of either of the above to one of fresh Portland cement. The materials must be thoroughly mixed, then just enough water added to wet the whole, and again well mixed. It should be laid evenly from 4 in. to 6 in. thick, and well rammed or beaten with the back of a spade to consolidate it. It must be mixed fresh, about, say, a cubic yard at a time; a little of the finest materials can be put on afterwards; this will fill up all holes, and give a nice finish. If well done this will look much like Portland stone, and last a lifetime. The ground should be prepared, of course, and all necessary drains and gullies first laid. The work must not be done in frosty weather, and should not be walked upon until quite hard.—H. W. M. X.

3923.—**Improving a Lawn.**—The method is very simple, but mainly depends on the cause of the failure of the turf. During winter keep it well rolled, and in the spring dress it with a good coating of wood ashes if procurable. Before the application of the above, sprinkle a quantity of grass seed, say, one bushel of renovating grass mixture, to be obtained of any good seedsmen, such as Sutton, Carter, Barr and Sugden, Hooper, &c., and add to this half a pound of Trifolium and White Dutch Clover. Where the mistake is generally made, is that people lay down a turf and think that is all that is required, and that it will take care of itself, whereas if there is a periodical sowing of seeds once in every three years, perhaps, and an application of manure from time to time, this will improve even the worst lawns, provided the ground is not soured by want of proper drainage.—GRAMEN.

3925.—**Salt as a Fertilizer.**—If the soil be dry naturally, salt may be applied more thickly than if the soil be cold and adhesive. In the former case 6 cwt. per acre may be given, and in the latter case 4 cwt. is, perhaps, enough. This would give, in the first case, about 1 lb. per rod; but in such a small way, perhaps, rather more may be applied with safety. We prefer to sow salt broadcast over the soil on a dry day as early in the winter as possible, and thus let it get thoroughly incorporated with the soil before planting time comes. Soot and lime may be applied in the spring to Potatoes with freedom, about 5 cwt. of soot to the acre being regarded as a liberal dressing, but if applied to a growing crop a second dressing may be given after there has been heavy rains. Whilst special Potato manures or guano are best applied in the furrows when the tubers are planted, it seems most advisable to have such dressings as salt, lime, and soot mixed equally with all parts of the soil.—A. D.

3927.—**Pruning Gloire de Dijon Rose on South Wall.**—This operation may be performed towards the middle of March if the weather is mild and likely to keep so; if severe, it will be wise to defer the pruning until the end of that month, as all Teas and Noisettes require later pruning than the hybrid perpetuals. The wood damaged by frost, misplaced and unripe shoots, and, in fact, all wood causing a crowded appearance should be cut away, and that remaining laid in regularly for blooming. The shoots may be shortened slightly, and it will be desirable to well mulch the roots with manure, as trees planted against walls require extra attention in this way, as the roots have only one side to extend and get support. Carefully preserve all new wood from the base, as climbing Roses are not unfrequently very "leggy," and then look unsightly. If properly supported new wood will appear from year to year to take the place of that worn out, misplaced, or damaged.—WILLIAM WALTERS, *Burton-on-Trent.*

3932.—**Gas Lime in a Garden.**—Your informant was quite right as to the greater efficiency of gas lime in the extermination of slugs, &c. A little discrimination is all that is required. If the ground is to lay fallow, a larger quantity may be used than if it is going to be cropped soon after the application. There could not be a better season than the present time of the year, for the gas lime could be spread over such land as is to be prepared for the forthcoming season's crops with less fear of any harm accruing to the future produce. Some people mix it up with their manure-heap, and so apply it altogether.—CALX.

—— Gas lime is a somewhat dangerous dressing to apply in gardens if in a crude or raw state fresh from the gasworks. The safest method of applying it is to mix with a barrowfull just double the quantity of soil from an old turf heap or rubbish midden. This should be turned about twice in the course of a month, and then the gas and ammonia being largely

absorbed in the soil, the danger to vegetation is lessened. At the same time it should be not less deadly to ground vermin. Where seeds are soon to be sown it should be used sparingly, and the safest plan is to give the seed bed a dressing of fresh but slacked lime when the seeds are sown, and another dressing at night when the seeds are coming up.—A. D.

3935.—**Planting Flowers.**—Bulbs of all kinds may be planted now; so may all kinds of Pansies and Violets. Daisies, Wallflowers, Primroses, Polyanthus, Sweet Williams, Forget-me-Nots, and other autumn-sown annuals may be planted any time from this to March when the weather is open and the soil works well. Then, in March, buy a small collection of hardy annuals, such as Candytufts, Escholtsias, Clarkias, Godetias, &c. Procure also seeds of Stocks, Asters, Zinneas, and Phlox Drummondii. Sow these latter in pots in a frame where there is as little heat as possible. Transplant the Stocks, Asters, and Phloxes early in May. The Zinnias are not quite so hardy, and may remain a little longer. Roses are desirable if the soil and climate are suitable. The former may be improved; but the latter, if laden with smoke, will be a bar to their full enjoyment. Carnations and Pinks may be planted in February; so also may hardy herbaceous or other plants—Delphiniums, Phloxes, Pyrethrums. Remember the old adage, "If you want a thing done well, do it yourself." Flowers require loving care.—E. H.

3936.—**Fragrant Roses.**—It is somewhat a difficult matter to say which are the twelve hybrid perpetuals most highly scented. At this season of the year, when we have not our friends to appeal to, it must be, to a certain extent, a matter of memory. I, however, give the following as possessing this, to my mind, a most essential point in deciding the qualities of a good Rose—viz: Monsieur E. T. Teas, Le Havre, Charles Lefebvre, Beauty of Waltham, Madame Charles Crapelet, Senateur Vaisse, Jean Liaband, La France, Alfred Colomb, Louis Van Houtte, La Rosina, Baron de Bonstellen, Duc de Wellington, Sir Garnet Wolseley, Exposition de Brie, Marie Baumann, Madame Fillion, Bessie Johnson, Madame Lacharme, Abel Grand.—WILLIAM WALTERS, *Burton-on-Trent*.

3937.—**Secateurs.**—These are among the most useful instruments ever introduced. My gardener has had a pair for the last three years, and with them he has manipulated some hundreds of trees each season. All the care required is that they should not be strained by being tried on too large branches, in which case the spring is apt to be strained. Secateurs cut ever so much cleaner than a knife, and do not require a hundredth part of the sharpening that the old-fashioned method of knife-pruning entailed. For the higher branches of standard trees there is a larger and more powerful kind of pruning shears, technically termed "Averruncators." These, however, are more expensive, but none the less lasting.—FORFEX.

3939.—**Wireworms in Pots.**—Too much care cannot be exercised in a proper supervision of potting sorts before consigning them to the pots. Prevention is better than cure at all times, as any future remedies may, or may not, prove detrimental to the plants. By this I mean the infusion of lime in water, and other remedies mentioned in most horticultural works. To remedy the evil afterwards, however, the best way would be to turn out the plants and pick out the miscreants, replacing the mould by some that has been carefully prepared.—VERMIS.

3178.—**Cloches.**—In answer to "Y. S.," I have read that the Cloches are made by Messrs. Breffit and Co., 83, Upper Thames-street, E.C., at the price he wants—viz., 10d. to 1s. each.—K. M.

3923.—**Improving a Lawn.**—Have all the weeds and Daisies removed from the lawn in March, then top-dress with a rich, light soil half an inch thick. Apply to a good seed-house, such as Carter's or Sutton's, state the size of lawn and nature of soil, and position. On receipt of order, a renovating mixture will be sent, arranged in suitable quantities of Grasses and Clovers, which, if sown thickly, will make a good lawn for croquet in the summer.—E. H.

3925.—**Salt as a Fertiliser.**—Thirty pounds of salt per rod may be safely applied to porous land. It is difficult to say how much salt should be mixed with a bag of soot for Potatoes, as soot is a less dangerous matter than salt, but in no case should the salt exceed the quantity per rod named above; the soot, of course, may be almost any reasonable quantity, from a bushel to a sack per rod. The salt should not be sown in the drills with potatoes; it should either be spread on the land and forked in, or else be sprinkled between the rows after the potatoes are up and hoed.—E. H.

3924.—**Butterfly Tulip.**—They are closely related to the Frittilaria, and the same treatment given to them will suit the Calochortes. At least, I have found them do best planted in light rich soil, of a rather sandy nature, and not disturbed too often. Plant in autumn, or as soon as received, covering the bulbs about 3 inches deep.—E. H.

3926.—**Orange Trees.**—Seedling Orange trees, unless grafted with fertile wood from another Orange tree, are a very long time in producing flowers. Better have the young tree grafted by some gardener, who could place the tree in a close frame or house until the union was perfect. Orange trees are not difficult to cultivate. They require clean, well-drained pots, and rich open loamy soil. Plenty of water during the summer, with less during the winter. They may with advantage be placed out of doors in the summer months. A greenhouse temperature suits them well. I am assuming that they are grown for merely ornamental purposes.—E H.

3928.—**Keeping Chrysanthemum Blooms.**—Chrysanthemum blooms will keep a long time in a dark cellar. I don't know that there is any secret in it. Of course the leaves die. I have kept them best with the stems inserted in damp sand. The blooms must be arranged thinly; if they touch each other they will be liable to damp. They must be cut before they begin to fade, but I may say I have never had occasion to keep them so long as three months.—E. H.

3929.—**Raspberries Blighted.**—How long have the Raspberries occupied the present site? In similar circumstances I should transplant to new soil. If that could not be done then dress heavily with lime and soot mixed together, and fork it lightly in. When used fresh both these substances are famous insecticides, and they sweeten and scour the soil.—E. H.

3930.—**Chrysanthemums for Pots.**—Large flowering Chrysanthemums, Prince of Wales, Mrs. Dixon, Mrs. G. Rundle, La Nymphe, Hero of Stoke Newington, Mrs. G. Glenny, Prince Alfred, Queen of England, Golden Empress of India, Mrs. Heales, John Salter, Princess of Wales, Venus, White Beverley, and Elaine. Pompones, Fanny, Celo Nulli, Helena, Salamon, Dick Turpin, Rosinante, Bijou d'Horticulture, James Forsyth, Automus, St. Michael, Mr. Astie, White Cedo Nulli.—E. H.

3931.—**Garden Walks.**—There is no cement of bright hue available for path-making. Would not a good sprinkling of powdered brick over the asphalte, when the path was formed, answer the purpose? If of too pronounced a colour, it might be strewed with ground sandstone. I think with the materials on hand a very good and pleasant-looking walk may be formed.—E. H.

3932.—**Gas-lime in the Garden.**—In reply to "Lumbricus," I have used gas-lime. I found no benefit in it, but, on the contrary, it caused sad havoc to Gooseberry trees, Raspberry canes, &c. Neither did it destroy the slugs, &c. Nothing would induce me to again try the experiment.—SUFFERER.

—— Gas-lime should not be applied to land cropped with vegetables, nor yet land just previous to sowing seeds, but it may be applied to vacant land now, and dug in at the rate of about one bushel per square rod, mixing it well with the soil.—E. H.

3933.—**Unfruitful Pear Trees.**—Does the Pear tree stand in a low unfavourable situation? If it does not I cannot understand why the flowers do not set, or at least some of them. Perhaps the soil is very light. How old are the trees? It is not easy to assign a cause for unfruitfulness without more information.—E. H.

3934.—**Plants for Clayey Bank.**—Plant creepers—such as Clematis, Periwinkles, some of the choicer Ivies. A few of the hardy climbing Roses would look well. Cotoneasters planted on or near the top would hang over and look well. A Pampas grass and a hardy Fern or two, such as Osmunda regalis and Lastrea felix—mas cristata would be at home, peeping up from amid the creepers. The Osmunda might be planted near the base of the bank, as it likes moisture.—E. H.

3938.—**Insects in Acacia Tree.**—Dress the parts affected with Stockholm tar (not gas tar). The former is a vegetable product, and will do no harm; not so the latter. Gishurst compound, softened down with warm water to a thick paste and rubbed over the parts, will probably kill the grubs or weevils.—E. H.

3939.—**Wireworms in Pots.**—Trap the wireworms with bits of carrot or potato inserted beneath the soil in the pots. Examine the traps daily and destroy the insects.—E. H.

—— In answer to a correspondent asking for the best means of destroying wireworms attacking plants in pots, I should suggest, if it were possible, without injuring the plants, that a careful search should be made at the roots for the worms, and that when re-potted one or two slices of potato, carrot, turnip, or beetroot should be buried about an inch below the surface. Each slice should have a wooden skewer stuck into it, by which it can be removed every morning for examination. If there are any wireworms present they will be sure to go to these baits. If the plants cannot be unpotted the insertion of these baits in the earth will be found very effectual.—G. S. S.

3984.—**Dandelions on Grass Plot.**—*W. S.*—Dig them up with a knife or spud whilst the ground is wet. In summer you can get rid of them by putting a good pinch of salt in the heart of each plant.

3985.—**Manuring Garden.**—My garden is an old one, of light, sandy soil, dark in colour. It has been heavily manured each year with cow manure. Would it be of benefit to change the order for one season and apply some kind of phosphate? If so, what kind and quantity?—B. G. [Apply a good dressing of lime now and a dressing of soot in spring, giving no manure this year.]

3986.—**Protecting Pansies and Iris.**—*Thos. Rogers.*—A thin coat of coal ashes on the surface of the soil is all the protection you need give them. Even this is not necessary in well-drained, warm soils.

3987.—**Plants for Conservatory.**—*S. S.*—As you do not state whether your conservatory is a small or large one, we are at a loss to advise you. Creepers suitable for a large house would be of no use for a very small one, and *vice versâ*. In a large house you could have tall Ferns, Palms, Camellias, &c., but these would not do for a house a few feet square.

3988.—**Winter-flowering Climbers.**—Will you give me the names of two or three winter-flowering Climbers best suited for planting out in a town garden?—J. G. [We presume you mean for out-door planting. There are but very few hardy winter-flowering climbers, but the following will probably answer your purpose: Chimonanthus fragrans, Jasminum nudiflorum, Forsythia viridissima, and Cydonia japonica.]

3989.—**Broad-leaved Myrtle.**—*Myrtle.*—Thin out the shoots a little, leaving those that are firm and well ripened, as it is these that produce blossom. If the plant is too high cut it back to the height you want it. This may cause it to bloom better in future.

3990.—**Marechal Niel Rose.**—*Myrtle.*—If you have a good border outside plant in it. You will have less trouble with it than with an inside border, and the Rose will probably do better.

3991.—**Soil for Bulbs.**—Will not decayed turf from a rather loamy pasture land, and well-rotted manure, with the addition of a little river sand, answer every purpose as a compost for bulb-growing in pots, as I have a difficulty in getting peat?—EARNUM B. [Yes.]

3992.—**Soil for Camellias.**—*F. W.*—Good turfy loam and sand, with a little well-decomposed leaf-mould, will do well for young Camellias. Peat will also do, but loam and peat in equal parts would be the best. Pot tolerably firm. Keep in an airy and light situation. Read articles recently given in GARDENING on the subject.

3993.—**Sandringham Celery.**—*Orange.*—From any good seedsman. You will find plenty of them in our advertisement columns.

3994.—**Pruning Medlar Trees.**—*R. H.*—They require no pruning.

3995.—**Horticultural Dictionary.**—*Seeley.*—Vol. I. of GARDENING and our query columns form the best horticultural dictionary we know of for amateurs.

3996.—**Herbaceous Plants.**—*One Willing to Learn.*—The twelve kinds you name are good ones, but they will not all flower at the same time.

3997.—**Melons for the Middle of June.**—We would sow a few seeds in the middle of January, and a few more a fortnight later. Conqueror of Europe is a handsome fruit when well grown, but is not considered so well flavoured as some of the newer kinds.

3998.—**Hydrangea not Blooming.**—I have a large Hydrangea in my greenhouse which bloomed well last year; this year it has made good growth, but has not bloomed. Ought I to cut it down—and if so, when?—E. I. W. [Let it remain as it is. It will probably flower well next year. If you cut it down you will cut off all your bloom buds.]

3999.—**Geraniums Losing their Leaves.**—*Charles H.*—Zonal Geraniums nearly always lose a quantity of leaves during winter. Water them only when dry, and never wet the foliage. Give plenty of air and keep frost at a distance.

4000.—**Treatment of Young Vines.**—*E. J. W.*—Much information on this subject has lately appeared in GARDENING.

4001. **Watering Ferns.**—Are there any Ferns, the fronds of which should not be watered? If so, what kinds? Also, is it better, generally speaking, to water the fronds as well as the roots of all Ferns that are either in pots under glass, or planted in a Fernery?—H. B. [The gold and silver Ferns (Gymnogrammas) should never be watered overhead, neither should Adiantum farleyense, or A. macrophyllum. Many Ferns with fine pinnæ are best not watered overhead. As a general rule ferns may in summer be dewed over with a fine syringe; and some of the kinds with thick leathery leaves may be syringed with some force to keep them clear of dust and insects. A moist atmosphere is necessary for Ferns, but at this season care must be exercised.]

4002.—**Cuttings Laurels.**—What month in the year ought Laurels not to be cut?—A. R. M. [They may be cut in any month with comparative safety. The best month is February.]

4003. **Achillea rupestus.**—*Sandgate.*—This is a hardy herbaceous perennial.

Names of Plants.—*W. Melron.*—1, Sedum of some kind; 2, Browallia elata; 4, Saxifraga sarmentosa.——*R. W. B.*—Acer cissifolia.——*An Old Subscriber.*—1, Echeveria secunda glauca; 2, Sempervivum tectorum; 3, Variegated Sedum; 4, Sedum carneum variegatum; 5, S. glaucum; 6, Saxifraga pentadactylis.——*E. B. H., Norfolk.*—Osmunda cinnamomea.—— *Gam.*—Stanhopea oculata.

QUERIES.

4004.—**Material for Garden Paths.**—Can any reader give any information about a material called porphyritic? It is a kind of gravel used for garden paths, and I am informed it answers very well. I want to know where it is to be obtained, and about the cost per yard, and perhaps some one could say where it might be seen laid down.—J. COCKBURN.

4005.—**Gentiana acaulis.**—Will any reader tell me how to raise this plant from seed?—H. B. T.

4006.—**Lilies in Towns.**—What kind of Liliums will do out of doors near a town? Soil, sandy and rich.—LEWISHAM.

4007.—**Pond leaking.**—Can anyone advise me as to the best method of preventing leakage from a small pond I have lately made? It is supplied by a stream which sometimes fails in summer, and the water soaks away rapidly. As I wish to grow water plants I do not like to line it with cement. Would "puddling" answer; and, if so, how, and with what should it be done? The soil is an ordinary loam, not gravel.—E. DE B. M.

POULTRY.

Brahma Fowls.—In regard to "T. F.'s" remarks in GARDENING, October 30, I beg to say I did not recommend Brahmas as fowls for small places; my remarks were confined to poultry as a profitable investment. "T. F." has made a mistake in recommending the Hamburgh family, as they are notoriously the very worst bearers of confinement as far as cleanliness goes. I can inform "T. F." I have kept two Brahma cockerels in a house 3 ft. square without run for two or three months, and they are perfectly clean and in excellent plumage. In regard to poultry as an investment, I think a farm of thirty acres as follows would, in the present state of agricultural pursuits, become a profitable undertaking: 15 acres of Grass, 7½ acres of corn, part seeded, 7½ acres of green crops, as Turnips and Potatoes, &c.; keep four milch cows, a strong pony, 1500 laying hens, three breeding geese, one gander; and during the summer months, if it was found that the land would keep more, young geese might be brought on, as many small farmers and cottagers in this locality sell them when beginning to feather at 2s. 6d. each. The land must be like this, cheap and contiguous to several good markets.—NORTH YORKSHIRE.

Fowls Cured by Paraffin.—One of my pullets a few days ago became very oppressed in its breathing. It was obliged to keep its mouth open, and was continually choking. I determined to use paraffin oil. I first inserted a dry feather in the wind-pipe, twisting it gently round to discover any trace of worms, which I could not. I then twice repeated this operation with an oiled feather with this result, that in two days the pullet was quite recovered. As I could not see any worms on the feather, I cannot say the disease was the gapes. Whatever the cause, the fowl was evidently in a bad way. I must add great care is evidently necessary in using the feather not to choke the fowl.—N.

Lameness in Fowls.—Kill your fowl at once; it is suffering from liver complaint, and will infect the others. When the liver is examined it will be found covered with small ulcers; there is no cure.—AN OLD HAND.

Fowls with Colds.—"Crooked Spire's" fowls have got the roup; he will soon cure them by using the following: One teaspoonful of strong alum water and a little cayenne pepper once a day, followed in twelve hours by a teaspoonful of castor oil. If the nostrils or eyes are affected, bathe and clean with same solution of alum water. I should also advise "Learner" to try the remedy, for it is a sure cure if taken in time.—GEORGE LITTLE.

—— In reply to "Crooked Spire," I should advise what I have just successfully tried, and have never found fail. My fowls had cold and coughs. I mixed in their hot, soft food every day for a week one teaspoonful of powdered ginger, one teaspoonful of hot curry powder, and two teaspoonfuls of camphorated chalk. Mix these well in before adding the hot water. In a week all were well but one chicken, it looked roupy about the eyes and got thin, so I killed it. As I have long found camphor a useful remedy for colds in human beings, I thought it must be equally good for fowls. I have never found this mixture fail, and camphorated chalk, as prepared for tooth powder, is the easiest and cheapest way of using camphor for fowls. I daresay black pepper would do instead of curry powder; the fowls always eat this mixture most greedily.—P.

Black Hamburgh Fowls.—In reply to enquiries about Black Hamburgh fowls, my experience is they are most profitable. I believe the great secret is to hatch early, and dispose of nearly all last year's birds before they begin to moult. We had a constant supply of eggs all through the severe weather of 1879-80. In 1879 I realised £13 9s. 8d. by keeping about thirty hens; expenses, including purchase of hens for sitting, wire netting, &c., £8 1s. 9d. A narrow wire netting with cut edge on the top of fencing keeps them in. I have two good cockerels hatched in April I would dispose of, with a few hens in good plumage, to start a beginner.—SHERWOOD FOREST.

Ascel Fowls.—Is this a new variety? I have never heard of the name before, except in the Crystal Palace catalogue. Would any reader give a description of this variety? A few birds of this kind were exhibited at the last show held at the Crystal Palace.—PETWORTH.

Purifying Feathers.—Would any reader tell me the best way of purifying poultry feathers for use?—T. S.

Turkeys with Swelled Heads.—I have some young turkeys put up to fatten, two of which have got large swellings on their heads. They have been carefully washed with warm water, but with no good effect. They are not "crammed," but eat as much as they like. They have been quite healthy up to now. Will any one tell me how to treat them?—M. E. G.

Books.—"Poultry for Prizes and Profit," by James Long. "Rabbits for Prizes and Profit," by Charles Rayson. Published 170, Strand, London.

Spanish Fowls.—I have a black Spanish cock, and during the last few months the white on its face has grown so much over its eyes as to nearly blind it. Can any reader give me any information how to stop the growth?—A CONSTANT READER.

Heat for Hatching Eggs.—Respecting "J. L.'s" inquiry regarding heat, in artificial incubation. As the result of months of accurate trial, I find that a heat of 90 deg. to 100 deg. is the most successful in every way, with plenty of fresh air and ventilation. I have hatched nearly every egg in a batch where temperature has been on an average 96 deg. to 98 deg., but have lost many batches by heat getting over 100 deg. to 105 deg., whereas, on the other hand, as low as 84 deg. on one occasion did not appear to affect the issue. With a heat of 100 deg. average the eggs will be truer to time, but birds weakly, some unable to hatch. By 5 deg. less, time will probably be a day or two longer, but better as regards results.—G. S.

—— I find that the proper temperature for hatching eggs is 102° to 104°; but 108° will spoil a few if it remains so for some hours. On the other hand, 98° will not spoil any if only let stop for a little time. Let 103° be the standard for the eggs. The common fowl takes 21 days; ducks, 28 to 30 days; geese, 28 to 30 days; turkeys, 30 days.—E. G. M.

Brahma Fowls.—I have a young Brahma cock, six months old. Will this fowl be old enough for breeding purposes by next month?—CONSTANT READER.

Fowls Diseased.—*G. W. R.*—Your fowls have probably got the roup. Read article in GARDENING, Dec. 18th.

Columbian Fowls.—Can any reader inform me where I can get the Columbian fowl, or how it can be produced, and what are its merits?—COLUMBIAN.

Fowls with Swollen Eyes.—Can any reader inform me how to cure a Spanish Pullet which I have? The flesh under the eyelids is all swollen up over its eye, about the size of a marble. It is not a bladder which Spanish fowls sometimes have. It stands moping about the yard with its head on its shoulder, and its comb is of an ashy-white colour. It appears to suffer from the cold and wet weather.—COLUMBIAN.

HOME PETS.

Curing Rabbit Skins.—I cure these as follows: Put the skins on a clean board, fleshy side up, and point 9 or 10 nails into the outer edge of the skin to stretch it. Put a tablespoonful of saltpetre and a pinch of alum into a saucer, pour half a gill of warm water into the saucer, and when the saltpetre and alum is dissolved, take a clean rag and rub the fleshy side of the skin with the liquid; rub it twice afterwards at intervals of two days; at the end of the week the skin will be cured and the fur unharmed, nor will there be the least smell from it. I have cured rabbit, hare, and sheep skins with such treatment, and the sheepskins have been washed and possed in the poss-tub to clean the wool, and the skin was none the worse for the possing.—R. B.

Canaries with Long Nails.—The long nails should be cut back about one half. Procure a very sharp pair of scissors, or, better still, a very sharp watchmaker's cutting plyers. Take out the bird, holding him on his back gently. Then draw out the claw, and, holding it at the joint of the nail, nip it, the nail, half off. Be careful not to wrench the nail, or it may injure the bird for a long while. To guard against this, let the joint of claw and nail be held between the left-hand forefinger and thumb. The best food for canaries, as a rule, is one-third summer Rape seed and two-thirds Canary seed. But if the birds are liable to diarrhœa, less Rape seed and a little Hemp seed may be given. At moulting time a little Saffron in the water helps them to cast their feathers quickly, and of course to renew their plumage equally quickly. If canaries are intended for breeding, they should get somewhat richer food in spring, as hard-boiled egg, a little Maw seed (unless constipative), and a little Hemp seed occasionally, but no green food, and, in point of fact, if Rape seed be given, they do not at all require green food. There should always be fresh sand on the bottom of the cage.—M. W. R.

—— If "Amateur" will take his bird out in his hand, and hold the claws up to the light, he will see a vein of red running partly through each; he may take a sharp pair of scissors and cut back to within about one-eighth of an inch of the termination of this vein. Do it carefully, or the result will be to make it bleed, which would of course cause pain.—FERNDALE.

Goldfinches and Canaries.—How can I get a goldfinch to mate with a canary hen? I have tried all sorts of ways, but never to any purpose.—T. SMITH.

Quassia Chip-Water for Canaries' Bath.—Would water in which Quassia chips have been soaked be injurious for a Canary's bath, as I think it would be good for destroying the insects? My bird always dips his beak several times before going in.—BETA. [We would not try it in the way you name. If you wash the bird in it you may do some good.]

Thrush not Singing.—Can any one tell me if there is any means of getting a thrush to sing? It is an early bird of 1879, and sang well last spring and summer, but it has not sung since moulting. It seems in perfect health. Is there such a thing as a bird organ? If so, where can I get one? Would this be a good time to teach him to sing a tune? I feed him chiefly on Barley-meal, with an occasional treat of worms or meat. I have lately given him a little crushed Hemp-seed, mixed with the meal. I keep it in a cool place, and put it out in fine weather.—DOLLY.

Lime-washed Cages for Canaries.—Will any reader inform me if lime-washed cages are injurious to Canaries? If so, what would do better than lime?—J. H. L.

REGISTERED FOR TRANSMISSION ABROAD.

SILVER FIR.
(PICEA NORDMANNIANA.)

THIS distinct and beautiful variety of Silver Fir was discovered by Prof. Nordmann growing on the summit of the Crimean Mountains; it was afterwards found to be common on the declivities of other mountains adjacent to the Black Sea towards the east, where it forms a majestic tree from 80 ft. to 100 ft. in height. Since its introduction into this country (some thirty-two years ago) it has proved to be one of the hardiest varieties of the Silver Fir. It commences growth late in spring, thus never suffering from the effects of spring frosts—a great recommendation for planting in low-lying situations, where many of the less hardy Conifers do not succeed satisfactorily. It is slow of development when young, and inclined towards a spreading habit; but when once planted out into permanent quarters, and its tap-root fairly established in the ground, it begins to grow more rapidly, and soon shapes itself into a well-balanced tree. In suitable soils it makes an annual growth of from 15 in. to 18 in. Deep, heavy, rich loam, resting on clay or rock, is the most suitable formation for its healthy progress. The contrast in its pale green foliage in summer between the old and young growths, and the beautifully glaucous coating underneath its foliage, is very effective; while the silvery appearance underneath its leaves is hardly perceptible in young plants unless closely examined, but when the tree is older, and upwards of 20 ft. high, this glaucous appearance is at once in striking and beautiful contrast with the colour of the branches on the upper side. The timber of this tree is said to be harder than that of the Common Silver Fir (Picea pectinata). The latter tree grows to a height of upwards of 140 ft., girthing 16 ft. at 5 ft. above the ground, and containing from 450 ft. to 550 ft. of timber; whereas Picea Nordmanniana only grows to a height of 100 ft. in its native habitats. Silver Fir timber does not command a high price, therefore Picea Nordmanniana can hardly be recommended to be planted with a view to its becoming a profitable timber tree; but, on the other hand, for its ornamental character, planted singly on lawns or in groups amongst other trees, it is one of the hardiest and best of trees belonging to the extensive family of Coniferæ.

NORDMANN'S SILVER FIR (PICEA NORDMANNIANA).

HARDY PLANTS FOR WALLS.

PERHAPS nothing in the garden is more objectionable to look upon than walls or buildings defaced by nail holes, the result of tacking up climbing plants, unless it be their sprawling about in the wild, uncared-for condition which they too often assume. No wall that has any pretention to neatness and finish should have a plant trained to it without either a trellis or strained wires, unless it be such plants as Ampelopsis Veitchi and the different varieties of Ivy, that cling with such tenacity, as not to require any other means of support than that which Nature has given them. A very fine and pleasing effect may be made by using these two kinds of plants alone in alternate divisions of 5 ft. or so wide, according to the space to be covered; but when this is done, it should be with the Ivies of neat, close growth, such as Hedera elegantissima and H. aurea, which, if clipped every spring, make fresh bright foliage. The contrast between these and the Ampelopsis is most striking, and particularly so during the autumn, after the latter becomes a rich claret colour, as it always does in a light, exposed situation. The only drawback which it has is its being deciduous, but by planting it, as above indicated, between ornamental Ivies, its foliage is not so much missed for the short time it is off as it otherwise would be. Those, therefore, who have walls they wish to cover with something really cheerful-looking, that will give them little, if any, further trouble, cannot do better than use these plants for the purpose; and if the soil before putting them in is well broken up, and a little rotten manure added, they will not be long in running to the top especially if assisted occasionally during the summer with soap-suds or other similar sewage, as their roots, being so close to the building, are not in a position to be benefited by any rain that may fall. On dwellings, most people have a desire for Roses, and charming wall plants they are, besides which it is the only situation in which some of the best of them can be grown successfully, owing to the shelter and protection they require. Take the Maréchal Niel for instance, the young foliage of which gets pinched and cut about when grown exposed as standards or on trellises, but on walls facing south or south-west they escape and flower profusely. The grandest display of this fine Rose I ever

saw was in a position of this kind; but, wherever planted, the thing is to encourage as much young wood of medium size as there is room to lay in, as it is from this that the whole of the flowers are produced. To spur this in or to prune as most other Roses are pruned is to cut these away, as almost every bud, except those at the base, contains a bloom in embryo, and it is the same with most other climbing Roses, all of which flower with much greater freedom when treated in the above-named way. The best plan for training these is to drive in some studs with holes in the end, through which to run the wires for support, and then get a strain from one end, that each may be made tight and fast. If these wires run along every second or third course they will be quite near enough together, and save the introduction of nails and shreds, besides giving greater security. For training Clematises, Honeysuckles, and other similar twining plants, wires strained vertically are best, as then they are in the right direction for the young shoots, which wend their way up them without any assistance. The great improvement that has been made in the first-named of late renders them very desirable as wall plants, a position in which they succeed admirably, and show off their magnificent flowers to great advantage. C. Jackmani and others of similar depth of colour are most striking on pale walls, the light backing showing up in capital contrast with the blue flowers, and red brick does the same for such delicate shades as C. lanuginosa and others of that class. To grow these really well they require great depth of soil, and not only this, but plenty of rotten manure as well, and to be liberally assisted when growing and blooming with water or sewage, which greatly prolongs their beauty. The flowers of these being made on the young growth, the way to treat them is to cut off most of that made the previous year, leaving only a bud or two at the base, each of them will start and again fill up the space made vacant. Some growers cut them entirely down, but that only answers for certain kinds, and for such as are grown in beds, but even with these it has a weakening effect, as they are so long denuded of foliage. Another strikingly ornamental plant for walls is the old Bignonia radicans, a plant that is not nearly so well known as its merits deserve. I well remember how much I was struck with it the first time I saw it in bloom, rivalling, as it did, many of the tender exotics grown with so much care under glass. The flowers of this fine old creeper are about 6 in. long, trumpet-shaped, and are borne in clusters at the ends of the young shoots, and as these are somewhat stiff and stand out from the wall 2 ft. or so, the whole are seen to great advantage. Bignonia radicans is a plant that requires a warm aspect and a light, dry soil to grow in, and if these conditions can be secured, it soon covers a large space. Before planting the best way is to drain the border at a good depth by putting in a layer of brickbats, which will quickly carry off surplus water during the winter, and raise the temperature several degrees; and if, in addition to this, the roots be kept mulched over in frosty weather, the plant will be rendered tolerably safe. Many of the supposed tender plants would stand a great degree of cold if protected in the above-named manner, as the collar and the main feeders are the parts first affected, they being very susceptible of injury from rupture of the bark and sap vessels after being frozen through when gorged, as they are then, with moisture. One of the grandest plants for a south wall is the Exmouth variety of Magnolia grandiflora, a truly regal plant, having leaves nearly 1 ft. long of a very bright pleasing green colour, and Tulip-shaped flowers as large as a basin, that exhale a strong perfume resembling that of a cut Lemon. Near the west coast and in favoured localities the Magnolia is sufficiently hardy to stand away from the protection of a building; it then forms large, handsome shrubs on lawns, but inland, and in colder districts, it is useless attempting its culture in this way, as, although it may escape for a time, it is sure to get destroyed in the end. A deep, light, sandy soil suits it best, and in this it ripens its wood, and flowers with more freedom than when it grows rampant with large pithy shoots. Lardizabala biternata, Ceanothus azureus, Escallonia macrantha, and Passiflora cœrulea will succeed in favoured situations, but are not to be depended on as permanent plants, one of the best of which for villa residences is Cratægus pyracantha; that does well on any aspect, and is highly ornamental when laden with its coral-red berries. The habit and growth, too, are all that can be desired for a wall, and the branches admit of training horizontally along on wires with the greatest regularity. For the sides of porches or other low, exposed positions of that kind, Berberis Darwini and stenophylla come in admirably, as they are very hardy, and have foliage of a bright, shining green; in addition to which they flower in the most profuse manner possible during the early spring months. The way to treat them is to spur them in immediately their beauty is over, so as to afford time for fresh young growths to form, on which they bloom the following year. S. D.

TOWN GARDENING.

FRUIT AND VEGETABLES.

I WILL now give a few hints on the culture of the Vine, the Strawberry, and the Vegetable Marrow, which trio will be found to be the most suitable in the way of fruit and vegetables to grow in town, and then proceed to window gardening.

The Vine.

Out-of-doors.—The great thing is to have a good situation. A Vine will grow and look green on almost any wall, but if you want fruit, and wish it to ripen, you must have a wall looking nearly due south. Moreover, your wall must not be shaded, at least for any considerable portion of the day by any high building, but be freely exposed to the sun's rays from morning to night. Supposing such a favourable position to be secured, however, the next thing to be considered if you want really to make a success of it is the

Border.—Now, though the Vine will grow and often fruit well in almost any kind of soil, yet if this happens to be too much or too little drained, too rich or too poor, your Vine may live, but will not do well; certainly will not give you any presentable fruit. So that unless the soil at the foot of the wall is suitable, or if there is any doubt at all about it, by all means make a proper border. The first point is to give the Vine as much root room as possible within reasonable limits. A border for such a Vine or Vines should certainly not be less than 4 ft. wide, and if it is 8 ft. or 10 ft. so much the better, but it need not be more than that. A suitable depth is 2½ ft. or 3 ft., and you should allow for drainage as well, and if you can raise the bed a foot or so above the ground level, so that all may be high and dry, and consequently warm, for low, wet soils or beds are always colder than high and dry ones—remember this in everything—so much the better. So that if you take out your bed as large as you can up to the size given and make it about as long as it is wide, unless more than one Vine is to be planted, then longer in proportion to the depth of about 2 ft. 6 in., and if necessary arrange a drain at that depth; it is better to do so in any case. The bottom of the bed should be made hard by ramming stones into it, or, better, making a concrete bottom sloping from both sides slightly down to the centre where the drain is. Put 9 in. or 1 ft. of broken bricks or other clean rubble on the bottom, and over this a layer of grass-sods or turves turned grass side down.

Soil.—Fill up with the most suitable soil you can get. This must not be too rich, or the Vine will make a rapid but soft and fruitless growth, nor must it be too poor and rubbishy. The best soil for the Vine is one naturally rich enough to supply all that is needed, and no more; so that a good sandy loam, rather inclined to be peaty, or else with a small proportion of peat mixed with it, mixed with only a small proportion of leaf-soil or manure, and a slight admixture of crushed bones, burnt oyster-shells, and soot if the soil comes from the country, is most suitable. It should be used in rather a rough state, and trodden in firmly, and also be made 6 in. or 9 in. higher than the ultimate intended level, as it is sure to sink.

Planting and Varieties.—The best time to plant is in spring, just when the young shoots are 3 in. or 4 in. long. The best kinds are, Early Black July, a fine Grape, Early Saumur Frontignan, white, and Royal Muscadine, amber-coloured. The Vine should be planted on a little hillock raised 4 in. or 6 in. above the general level of the bed, for this and all fruit trees cannot endure to have the collar at all buried.

Training.—As to the training, much depends on the height or length of your wall, whether there are any windows in it, &c. Of course if it is a very high wall and the Vine is to reach the top, you must not spread it out laterally nearly so much as if the wall were only 5 ft. or 6 ft. high, and in such a case the Vines must be put pretty close together, say 5 ft. or 6 ft. apart if the wall is over 12 ft. high, and the main shoots or rods had better be trained up vertically; four or five of these will be sufficient. If the wall be low, then let the main shoot run up to the top without stopping; take out the point and prevent its going any higher, select three or four of the strongest side shoots from this on each side, and pretty nearly equi-distant from each other. Train these out laterally or horizontally, and if the wall is not more than 6 ft. high, these side rods may reach to 10 ft. or 12 ft. on each side, but not all at once. When you have got your Vine into shape, that is, as many leaders or rods as you want fairly started in their proper places, let them grow the first year as they like to a length of 6 ft. or 8 ft., then take out the points; this will be about July. They will not grow much more after this, but the strength will flow into the buds forming at the axils of the leaves along these shoots. When pruning time comes, that is, always when the leaves have all fallen in autumn, cut all these long rods back to about 2 ft. from the base, or 3 ft. if very strong. In the spring every bud at the axil of each leaf will develop into a shoot, and these secondary side shoots are those that produce the fruit, though they will not have any to speak of the first two or three years, that is, if the plant was a young one. When these side or fruit-bearing shoots have developed three full-sized leaves stop them, and continue to stop all future shoots from these or any other part of the plant all through the summer, except the one at the end of the main rod if it is a strong one; if not, take it out and take the nearest vigorous one you can get. Train this so as to form a continuation of the rod; stop it at 6 ft. or 8 ft. and cut it back to 2 ft. or 3 ft. again in the autumn, so as to let the Vine extend only about 2 ft. each year. In this autumn pruning all the side shoots or spurs must be cut back, leaving only two, or at most, if the second bud is not strong, three buds from the base. In spring each of these will produce a shoot, and just as they start you must go over them, and pinch out all but the strongest and fattest looking, leaving only one. These will, the third or fourth year, show fruit at the third or fourth joint, and as soon as you can see the blossom, pinch out the point of the shoot at one joint beyond the fruit, and all barren shoots to be severed the same at the third or fourth joint. Now you have the whole system at a glance; the main rods trained straight and equi-distant either horizontally or vertically, as may be most convenient, and the side shoots, bearing the fruit, regularly thinned out in spring, leaving only the one most likely to bear fruit, these stopped and in autumn pruned back. As soon as a main shoot or rod gets worn out, from the excess of eyes formed, which will be after three or four years of fruit bearing, cut it right out, and induce another young one to take its place springing from the base. There are other systems of training Vines, but this is, in our experience, the best, at least for out-door work. What is termed the "long rod" system is very good, but more suitable for Vines under glass.

Watering.—Plenty of water must be given at the roots, especially in such a made and drained border, just when the fruit is swelling, but only if the weather is dry and artificial moisture is needed, as the Vine does best in a somewhat dry soil; and you cannot syringe the foliage too often in dry weather, except just when the Vine is in bloom and setting the fruit, when it is better to be kept dry, and, of course, when the fruit is ripening no moisture is needed.

The Strawberry.

Strawberries may be grown in an ordinary bed in the garden, as in the country, but we

should strongly recommend a higher and more favourable situation, such as a raised bed, or one made on a flat roof of an outhouse or on the house itself. Strawberries do not require a great depth of soil to grow and fruit in, so that a bed made in a good-sized box or case, 1 ft. or more deep, and as large as possible, or a raised bed with boards for the sides, will suit them capitally. Some inches, as many as you have room for, of gravel or "ballast" should be placed in the bottom, over that a layer of Grass sods or spent Hops, and then fill up with good loam, rather inclined to be sandy, with a small admixture of very old and decayed manure or leaf-mould, put your plants in 1 ft. or at most 15 in. apart, or even less, for you will do best with small crowns close together, especially where room is limited, and make the soil very firm, indeed hard. We advise planting in spring, for these and for everything else in fact, so that the plants may get a good hold on the ground before winter. Protect them with litter or in some way in winter; in fact, if you can do it, it is far better to have glass over them at this season; the plants will bear next spring. Any kind will do that is vigorous and free bearing, and a late kind rather than an early one, so that it is hardy as well. Syringe the plants pretty often when starting and again when the fruit is swelling, and at this time supply what sustenance is necessary by means of frequent soakings of liquid manure at the root, taking care that the liquid does not touch the leaves or fruit. Of course the plants must be exposed to the full power of the sun at all times, or there will be little or no fruit.

Propagating, &c.—Take layers off into 3-in. or 4-in. pots at the proper season, setting the pots on the bed, and a stone on the runner to keep it in place till rooted; and stop the runner beyond the pot. As soon as well rooted and established, separate them from the old plants, and stand or plunge them close together in a sunny place either for the formation of new beds, or for shifting into larger pots to be fruited there. Strawberries in beds must have all runners that are not required for propagation removed as soon as they appear; they must be kept well weeded and the surface occasionally stirred, though the soil must be made and kept firm. Do not let a bed stay after it has fruited for two years, but make a new one. Just as they are starting the second year give a top-dressing of rich soil, and do not stint them of liquid manure when the fruit is set, especially if the weather is dry.

In Pots under Glass.—If you have a greenhouse or a frame or two, plants grown in pots under glass give the best results. The layers for these are rather better taken from beds; you can very likely purchase them, but you can get them from pot plants as well if there is no other way. Layer them into large 3-in. or 4-in. pots as early as you can, using a nice rich sandy loam and not much drainage. As soon as rooted, separate them and stand close together on or plunge in ashes in a sunny place. See that they have enough water, and when the pots are full of roots shift into 6-in. pots, and plunge or stand as before out-of-doors. Give them plenty of water, and when getting pot-bound give liquid manure pretty strong at every other watering, and vary the nature of this as much as you can, using manure water, soot water, guano, &c., in turn. As soon as the air gets dirty, about October, remove to a cold frame or house and plunge in ashes or hops, &c., close to the glass, and do not crowd them too much. Give plenty of air, and in spring a few may be removed to a sunny shelf of a greenhouse, and liquid manure and water given as required when they start into growth, or a frame with a bed of gently fermenting material be prepared and filled with some of the forwardest of them, plunged in March or April; these will fruit early, but do not let the roots get through the pots into the manure, &c., beneath, or you will have nothing but leaves, and fine ones, too; or they may be left to fruit in the cold frame. The main thing is to get the plants well ripened and hardened in the open air in autumn for the next year's fruiting. Do not over-water them at that season, but give enough to keep the soil just moist and prevent the plants flagging. Always prefer plants having one rather smallish, but firm and prominent central bud or crown.

Vegetable Marrows.

The way to grow these is to have a raised bed, with plenty of nice, sweet, fermenting materials underneath, in a warm and open situation, and yet protected from cutting, and especially from east, winds, which are most injurious in town gardens. Nothing is better than stable manure, if this can be had, though it must be well sweetened before use. Put a barrowful of good loam, with some leaf-mould or decayed manure, on the top, and if you are in good time, not later than the middle of May, sow the seeds on this under a hand-glass or a bottomless box, and a sheet of glass over it will do well. When up, and the second rough leaf is formed, throw away the weaker ones, and plant the two strongest and stockiest as far apart on the bed as you can; if the bed is small, one plant will do. Cover them over with the glazed boxes till they have got a good start and begun to run; then remove. Give water (tepid) when needed, and by the end of June and in July they will make a wonderful growth. Do not stop them, but let them run, though if so many fruit begin to swell on a single shoot that it cannot supply them, and they begin to turn yellow or drop, take out the point, so as to throw the strength into the fruit.

Give plenty of water, and syringe the foliage frequently. Good fruit can also be grown by planting in good-sized boxes or artificial beds on a flat roof, and they will often do better on such a raised position than down on the ground. Put plenty of drainage in the box, and fill up with a mixture of equal parts of good loam and manure in a half decayed state or fresh, so that it is sweet is best.

Plant the Marrows out in June. Where no special hot-bed is made early enough to raise the seeds, this can be done in pots or boxes of sandy loam and leaf-mould, placing them in a frame with gentle heat, or in a greenhouse, or a warm kitchen window. When the first rough leaf is formed, pot off singly into large 3-in. or 4-in. pots; harden off, and plant out in the boxes or beds early in June, or earlier if there is any bottom-heat. But there is no absolute necessity for this latter. We have seen some of the finest plants and fruit produced by putting a couple of plants into a frame that had been used for raising bedding plants; when these had been removed and the heat had subsided, the lights were kept on for a time, and when the plants began to run outside taken away altogether. We have found Moore's Vegetable Cream and the Long White the best kinds to grow.

B. C. R.

THE LAW RELATING TO GREENHOUSES.

With regard to this question, the law on the subject shortly stated appears to be as follows: By the 38 and 39 Vic., chapter 55, sec. 157, it is enacted that every urban authority (*i.e.*, the Local Board) may make bye-laws with respect to certain matters therein specified, one of which is "with respect to the structure of walls, foundations, roofs, and chimneys of new buildings for securing stability and for the purposes of health," but nothing is said about greenhouses. These bye-laws when made are required to be submitted to and confirmed by the Local Government Board, and are required to be printed and hung up in the offices of the local authority, and a copy delivered to any ratepayer of the district to which such bye-laws relate on his application for the same, and to be open to the inspection of any ratepayer of the parish at all reasonable hours (see secs. 184 and 185 of the same Act).

It is by virtue of these bye-laws that the surveyors of the local authority interfere with the erection of "greenhouses," although it is questionable, judging from the wording of the Act, whether it was ever intended that such a class of buildings should have been affected by it; the buildings contemplated by the Act clearly mean buildings intended for habitation. The question therefore resolves itself into this: "Is a greenhouse a building within the meaning of the Act?"

As I have said before, the power of confirmation of bye-laws rests with the Local Government Board, but it is provided by the 182 sec. of the above Act "that no bye-law made under this Act by a local authority shall be of any effect if repugnant to the laws of England or to the provisions of this Act;" therefore I take it that not even the approval of the Local Government Board could be held to justify the enforcement of any bye-law which might be shown to be repugnant to the provisions of the above-mentioned Act.

The above applies to places out of the metropolis, but as many parts of the suburbs are just within the limits of the Metropolis Local Management Acts, I append such information as can be gained upon the subject in these Acts.

By the Metropolitan Building Act, 18 and 19 Vic., c. 122, as to the regulation and supervision of buildings, it is stated in the list of exemptions from the operations of that Act, that "all party fence walls and greenhouses, so far as regards the necessary woodwork of the sashes, doors, and frames, shall be exempt from the operation of the first part of that Act." This is the only mention that I can find of a greenhouse, and the questions to decide are, is the above exemption a complete exemption, or only a partial one? and is a greenhouse a building within the Act? If it be only a partial exemption, then all the other portions of a greenhouse not being sashes, doors, or frames must conform to the regulations of the Act which relate to the structure of buildings, and which enacts that "every building shall be enclosed with walls constructed of brick, stone, or other hard and incombustible substances." G. W.

The Milk Thistle.—This old native biennial or annual plant should find a place oftener in our gardens in these days of fine-foliaged plants than it does. It is a hardy, easily grown

Milk Thistle (Silybum marianum).

biennial, and raised readily from seed. It looks exceedingly well in the mixed border before the flower-stems spring up. It is, however, most suitable for growing in a semi-wild state on dry banks and similar places. It has large and handsome shining green leaves variegated with white.

House and Window Gardening.

MY GARDENING FAILURES.

I read Gardening every week, and occasionally its perusal inspires me with hope; more frequently it plunges me in what I may call poetically an abyss of gloom and blank despair. All this may sound uncomplimentary, but it arises from the fact that I am passionately fond of God's choicest gifts—flowers, and am at the same time an ass. An ass I dub myself, inasmuch as year after year I strive to work out horticultural problems which in theory seem as easy as the traditional A B C, only to find that in their practice "that way madness lies." Furthermore, I spend much valuable commodity, money, to wit, in the purchase of choice plants, and when I find them at the expiration of a few weeks "faded and gone," a charming and highly satisfactory result which always follows, I again call myself an ass, because I might have bought much Tobacco with the money, and asphyxiated myself, or at any rate cultivated heart disease.

With your permission I will give you two specimens of my good fortune. Last year I bought many hundreds of bulbs, paying a high price at a first-class seedsman's, and carefully planted them about the end of October in my little garden. I followed out all the popular notions most scrupulously with regard to the

conditions of soil, the depth at which I planted my bulbs, &c., and this was the result. Crocuses flourished magnificently, that is, until the flowers came. Then, ah then, fowls of the air descended in the shape of sparrows, and from early morn, when I was of course asleep, until dewy eve, or at such periods as I was not "armed" with a small pistol, they waxed fat on my golden flowers, and exterminated the purple and white ditto in their vigilant search for more yellows. This I did not grumble at, because, as my wife says, it was my own fault for planting them. Besides, sparrows look cheerful about the garden, and their melodious chirp at early morning, particularly if one has been burning the midnight oil (as is frequently my fate) and one wants sleep, is invigorating, and teaches one the beauties of patience.

With regard to the other bulbs, one perhaps in every six came up. Some flowered and some didn't. Those that flowered were very "'ornary" specimens, as some one hath it, and of those that did not, it is unnecessary to enter into description of the beauties of the blossom. Then I bought seeds; and, sir, picked out packets with some of the most terrific names I could light upon. The result in their case was a wilderness—a lovely wilderness where flowers gave way to foliage, and quite right and proper too. Geraniums made "leaf" and "wood" to perfection. Bloom was at a discount. That of course did not matter, because plenty of foliage and lots of wood does away with any trivial disappointment in the matter of blooms. At any rate I had to persuade myself that it must be so.

This year I have built myself a greenhouse. Now, thought I, miserable ass that I was, shall I have flowers. I bought Ferns, Primulas, Camellias, Bouvardias, Cyclamen, Palms, India-rubber plants, Oleanders, Geranium, Heaths, Hyacinths, Tulips, and really more things than I care at the present time to contemplate. Result: Camellias have generously shed every bud they possessed; Ferns turned brown and withered; Primulas have run up into tall stalky plants, something like Lettuces run to seed, lost all their original colour, dwindled in the flower until the blossom is only half the size it originally was, and generally gone wrong; Cyclamen have likewise turned over the wrong leaf, literally; the flowers have withered, the stalks become sappy and soft, and seem to me, in my asinine capacity, as though they were in want of a tonic; Geranium trusses have died down, and the plants appear to be suffering from jaundice, as all the leaves have turned yellow.

My house is a lean-to, heated with a stove and hot air pipes running all round it, and out at a chimney at the back. I endeavour to maintain a heat of 60°, but candour compels me to admit that it occasionally differs.

Would some kind friend, eschewing all technical terms, for they drive me crazy, tell me in good round Saxon the cause of my repeated failures? Likewise say what would really flourish, and what would inevitably fail. I might thus have a chance in picking out a fresh stock from your advertisement columns of choosing something which would not end entirely in DISAPPOINTMENT.

Camberwell.

Aucubas for Windows.—Small, compact plants of the various forms of Aucuba, when well furnished with berries, are much valued in London during winter for window decoration. The way in which they are chiefly obtained is by fertilising old-established plants with male pollen, and then layering in light sandy soil, good-sized branches with bushy heads being selected for the purpose and pegged down. In a short time they strike root, when they are severed from the old plant, and in autumn are lifted, potted, and placed indoors to colour their berries. Standard plants are obtained by grafting on the common Aucuba.—S.

Myrtles.—These are among the best of window plants when kept fresh and growing. They will stand a good deal of rough usage, but in order to have them in good health they should be grown in turfy loam and sand, and be frequently syringed to keep them clear of dust. They need plenty of air, and succeed best in the window of a cool room. During summer they are best placed out-of-doors. The common Myrtle (Myrtus communis), which we now illustrate, is the kind generally grown in windows, but the double-flowered kind is by some considered much more beautiful. A neat bushy plant looks very nice when in bloom, but the beauty of this Myrtle is much enhanced if trained as a standard with a stem about 2 ft. high. However, as the double-flowered Myrtle grows rather slowly, it is a good plan to graft it on the common broad-leaved kind (Myrtus communis), of which rooted cuttings, when planted out in suitable soil, make in one season plants fit to be grafted on at the above-mentioned height. The best time to perform this operation is in the end of August or beginning of September, when the branches of the Myrtles are sufficiently ripened, and the plants must be kept in close air until the scion has taken, after which period they may be treated as is commonly the rule to deal with plants under such circumstances, that is, to gradually harden them off, to untie the ligatures, and to cut away the branches of the stock. It must be understood that all the branches must not be cut clean off at once, as that would very likely cause the death of the plant from overflowing of sap, while, on the other hand, these branches assist to strengthen the trunk until the scion has grown sufficiently to consume all the

Common Broad-leaved Myrtle (Myrtus communis).

nourishment the roots furnish. Care must be taken to get a well-shaped crown, therefore a judicious stopping of the branches must be made in time, and, of course, they must be pruned annually in spring by cutting back the strong ill-placed shoots, so as to cause them to form a bushy well-shaped head.

WINTER AND SPRING FLOWERING PLANTS.

THOSE who make a point of furnishing their dwellings with flowering plants during summer, and who have no glass accommodation, except ordinary garden frames, often feel much at a loss in winter for material wherewith to maintain their indoor decoration; but, by the use of a good-sized frame, say three or four lights, the length of time during which they enjoy these flowering subjects may be greatly lengthened by always having something in bloom from the latter part of winter through the spring, provided the right plants for the purpose are selected. It must be borne in mind that I am now treating of such plants as will only require protection from frost, with no artificial heat whatever; and, therefore, it is essential that the subjects employed are all but proof against damp, as in a hard winter it frequently happens that the frame will require to be kept closed, or almost closed, for several weeks together, the lights being covered with a thick coat of Fern, litter, and mats, and the sides also surrounded with as much litter as will keep out frost.

Amongst the first plants that I should recommend for this kind of treatment are the different varieties of Primula cortusoides, than which nothing can be more beautiful early in spring; their flowers, which are produced in profusion, vary from white to the deepest lilac, almost approaching crimson; these Primulas will live in the open ground in favourable spots, but they never flower so finely as they do when grown in pots; 6-in. or 8-in. pots are large enough for them; they should be well drained, and good loam should be used with a little leaf-mould and sand. The Japanese Primula (P. japonica) is suitable for associating with them; this, in proportion to the size of the plant, should have plenty of root-room, the soil, too, should be well enriched with rotten manure, and manure water should be applied freely when the plants are in vigorous growth. Thus treated they will make leaves as large as the hand, with flowers proportionately strong; the whole plant, indeed, will be so different from what it is usually seen when confined to small pots with insufficient sustenance, as to assume quite another character.

Some of the laced forms of Polyanthus will form suitable companions to these, making handsome window plants, as do also the common double white and lilac Primroses; different varieties of Myosotis, of which dissitiflora is one of the best, also succeed well under similar treatment; the pots for these need not be larger than from 4 in. to 6 in. in diameter. Hepaticas, naturally early flowerers, will come into bloom in a cold frame a month or six weeks earlier than in the open ground; the beautiful double blue and pink varieties are two of the best, their flowers lasting long in a cut state.

Dodecatheons (American Cowslips), of which there are several beautiful kinds—white, lilac, and violet—likewise do well in cold frames, and are amongst the most distinct and beautiful flowers which one can possess.

Campanulas, though not early bloomers, should likewise have a place in this frame of specialties. The elegant drooping C. fragilis, both blue and white, are amongst the very best plants that can be grown for a window, blooming, as they do, in such profusion as to almost hide the leaves of their pendent shoots, and, when their principal flowering season is over, still giving a succession, though less in quantity, up to late in the autumn; 6-in. or 7-in. pots are large enough for them. The stately C. pyramidalis is a perfect contrast in every way to the foregoing, its flower-spike forming an elegant pyramid, that, when well grown, with plenty of pot room, will attain a height of from 6 ft. to 10 ft.; there is no plant grown that is more effective in a hall or on a staircase, and during the time of its blooming, for several weeks, it will do with less light than most plants. Both the blue and the white varieties should be grown; they require liberal pot room, say pots from 9 in. to 13 in. in diameter, according to the size which the plants are required to attain. These are biennial, and, if propagated from suckers in spring, or raised from seed, as previously recommended, they will come in most usefully next summer. In the case of these, as well as the other sorts of Campanula just named, care should be taken to pick off the capsules as the flowers fade, otherwise they are sometimes liable to communicate decay to the advancing buds; good ordinary loam answers best for them.

A few of the better varieties of Pansies I would also recommend, but they should consist of the best and most distinctly-coloured show kinds, which are vastly preferable to the magpie-coloured fancy sorts. Although naturally early-flowering plants, when grown in pots they come in some weeks sooner, and, not being exposed to the beating rains and cutting winds of early spring, have a fresher appearance than those seen at that season out-of-doors; another advantage is that where the flowers, which are serviceable for cutting, are so required, their stems, when grown in this way, are considerably longer than those of outdoor blooms.

As a matter of course, Violets should be included, the Czar and the Queen of Violets being two of the best for the purpose; they succeed well in ordinary loam, with some manure and leaf-mould; Pansies thrive most satisfactoilry

in fully one-half vegetable mould mixed with loam; in both cases enough sand should be used to ensure porosity; 5 in. pots for the Violets, and 7 in. or 8 in. for the Pansies will be found to be sufficiently large.

As regards Dielytra spectabilis and its white variety, if moderate-sized roots are now taken up and placed in 8 in. or 9 in. pots, they will bloom several weeks before those out-of-doors, producing their handsome drooping sprays unscathed by spring frosts. The pendent blooms of this plant are never seen to greater advantage than when hanging from the sides of a vase mixed with other flowers. To these should be added Scillas (including S. sibirica, S. bifolia, S. campanulata and its white variety) and Dog's-tooth Violets (both white and rose-coloured kinds). Hyacinths, Narcissi, Crocuses, and Snowdrops, as a matter of course, should receive attention, as many of them being grown as the frame or frames will hold. The whole of the above plants should be plunged in a bed of ashes inside the frame. Thus managed, they will require less attention in the way of watering, and be much less liable to suffer through the effects of frost, should any mishap occur so as to cause its getting inside the frame, which should stand in a sheltered place, but, above all, thoroughly exposed to the light, and under the full influence of all the sunshine that at this dull season can be got; to still further admit of the solar rays exerting an influence over the growth of the plants, the frame ought to be well raised at the back, so as to make it slope abruptly to the south; 18 in. of straw should be packed round the outside, and kept in its place by stout stakes driven into the ground; dry litter ought also always to be at hand to lay over the glass.

In covering frames in winter, I have found it best during severe weather to first lay mats on the glass, then 6 in. of litter or Fern, and another thickness of mats on the top, and if light wooden shutters or light frames, on which have been nailed some ordinary asphalted covering, be laid on the top of all, the whole will be kept dry, which is a great desideratum, as when covering material is dry it wards off double the amount of frost it is capable of doing when wet; by laying mats under the litter in the way described, the glass is kept much cleaner than it otherwise would be—an important matter, as the more light the plants get the better. Air in abundance should be given on all favourable occasions, and care should be taken to keep the ashes in which the pots are plunged as dry as possible. From a frame such as that just described, with the plants fairly attended to, a great deal of pleasure, as well as a good supply of flowers, may be had, that will go far to while away the dreary months until blossoms are more plentiful out-of-doors.—B.

GLASSHOUSES AND FRAMES.

A FEW HINTS UPON THE CULTIVATION OF ORCHIDS.

HAVING been amongst Orchids for a considerable time, I thought a few remarks how I grow them would not be out of place in GARDENING ILLUSTRATED. Taking, for example, the Dendrobium nobile, D. Gibsoni, D. fimbriatum, D. densiflorum, and D. chrysanthum, which are equalled by few and certainly not surpassed in the beauty of their flowers by any other Orchidaceous plant, and if the undermentioned directions are resorted to, they will be found very easy of cultivation.

All Orchidaceous plants require to grow them successfully a season of rest, a season of flowering, and a season of growth, all of which should be as near as possible to the seasons of those parts of the globe which they so profusely inhabit, and the above named varieties should especially be subjected to a change of treatment as mentioned above, otherwise they will never flower to perfection.

As is well known, three seasons are only mentioned in India—the hot or dry season, which is succeeded by the rainy season, and then follows the cold or winter season. In the hot season almost all the varieties of Orchids produce their flowers; in the rainy season they make their growth, and during the cold season they have a period of rest. It is an easy matter to imitate the different seasons in our Orchid houses, and by adhering to the simple rules we could flower the above genus at any time of the year required. The Dendrobium nobile, chrysanthum, Pierardi, &c., grow well when fastened on pieces of wood with copper or metallic wire. Oak branches with several arms or forks protruding in different directions are the most suitable wood for them. When the plants are making their growth, a little Moss should be fastened to the wood for the young shoots to root into.

A strong moist heat is necessary in the growing season, when they may be often slightly syringed overhead. They may be propagated by taking one or more of the stems while in a dormant state, taking care not to injure the roots, and carefully potting it in turfy peat and Sphagnum Moss, and not much raised above the level of the pot, which must be carefully drained, then plunged in a gentle bottom heat of Cocoa-nut fibre, when the plant will speedily produce young shoots.

The flowers of all the Stanhopeas are more or less fragrant, and the following method of culture will be found easy and successful: Over the drainage hole of the pot about to be used place one of a smaller size, generally covering about half of the bottom of the pot; around this is placed a quantity of broken pots, filling the pots three parts full. Next select a sufficient quantity of fibrous peat and place it on the drainage, none of the pieces being less than the size of a Walnut. In placing these, care must be taken to leave a passage for the water to escape; this may be more effectually secured by introducing a few pieces of broken pots between every layer, more or less according to the size of the plant; in fact, it is a good plan to continue the broken pots all the way up the centre to the bottom of the pseudo-bulbs after the peat becomes level with the top of the pot; the external layers of peat may then be made fast with small pegs of various sizes. These pegs penetrate the lower layers of peat and secure the whole firmly together. About 6 in. above the edge of the pot the plant is placed on the top, the roots carefully laid out and covered up to the bulbs with smaller pieces of peat and Sphagnum Moss. Continue to fasten with pegs, as before mentioned, until it is 9 in. or 12 in. above the level of the pot.

When a single pseudo-bulb is first potted it should be but slightly raised above the pot, but as it grows larger it may be progressively elevated. Unless the plants are very healthy, water is given but sparingly at the roots, and in winter very little or none is given. Great care must be taken to preserve the roots, which by overwatering, especially in winter, are almost sure to be destroyed. The general temperature of the house ought to range from 60° to 85°; in the afternoons of the growing season it must be closed early and the paths well watered, and occasionally a little water sprinkled over the plants. It is a great advantage to have a bed of Cocoa-nut fibre in the house in which to plunge the pots, as the heat from it circulates through the peat and potsherds and causes the specimens to grow with great luxuriance. Young plants are obtained by taking of one or more of the bulbs and potting them as recommended above. CHAS. WOOD.

Cool-house Orchid.—Almond-scented Odontoglossum (O. madrense).

An Almond-scented Orchid (Odontoglossum madrense).—This is undoubtedly one of the most distinct and handsome of all the species of a deservedly popular genus of cool-growing or greenhouse Orchids. Its flower-spikes bear from five to six snow-white flowers of wax-like—indeed almost leathery—texture, both sepals and petals being blotched with clear chocolate-purple at the base. The lip is cordate, having a bilobed crest, and is blotched with lemon-yellow and mottled with orange. Each flower measures 2 in. in diameter. The accompanying illustration was made in Messrs. Veitch's collection at Chelsea, where its deliciously Almond-scented flowers lasted from six to seven weeks as fresh as when they first opened.

Seedling Gloxinias.—I find these to make the best of flowering plants for rooms or for table decoration. I sowed two small packets of seed on February 20 last, and when the plants were large enough to handle, I had them dibbled into small pots and put on a front stage in an early Vinery, potting them on as they required it into 5-in. pots. The best plants commenced flowering the first week in July; on the 14th of July I had sixty in flower, and every one quite distinct. Some of the plants measured 20 in. across, and some of the flowers 4 in., and since that date I have not been without Gloxinia blossoms. Early in September I moved some plants into the stove, which soon came into flower, and the remainder will come in in succession, so as to keep up a supply through the winter.—W. W. P.

Sonerila Hendersoni. — This winter-flowering plant and its varieties (six in number) now rank amongst the most attractive occupants of warm greenhouses in the London nurseries. Their foliage is richly marbled and shaded with silvery-bronze, whilst their flowers, which run through all shades of violet, mauve, and pink, are produced in great numbers. They are well adapted for growing in pans, baskets, or vases; and even in 3-in. pots, handsome, bushy, little plants of them may easily be had. Grown in the latter way, a number of plants, some of which bear over thirty spikes of blossom, form an attractive fringe to Palms, Dracænas, and other fine-leaved plants.

VEGETABLES.

French Beans in Winter.—We have generally a fair supply of French Beans out-of-doors till November 1. By that time those which were planted in a low pit about the middle of August are ready for use. These are followed by a later sown batch in the same pit, and after they are done, those sown in pots come in. The earliest in pots are fit for use by the first or second week in December. Another sowing is made to succeed these and to come in at Christmas, and after that sowings will be made every three weeks until the middle of March, which will give a constant supply of

Beans until after Easter. French Beans are not difficult to force. For some time I have always sown the seed in 4-in. pots, and when the young plants were about 6 in. high, shifted them into 8-in. ones. With six or eight in a small pot, I found that they became very much crowded before they were many inches high, and that the pots became so full of roots that they required water nearly every hour in the day, and if they chanced to become the least dry it checked their growth very much; but now I never start them in small pots, but sow the seed at once in the pots in which the plants are to remain. Several dozen of 8-in. pots are cleaned, and about 1 in. deep of crocks is placed in the bottom of each; the soil, which consists of one-half loam and the other half leaf soil, is then placed over these to the depth of 3 in., and made very firm. Seven or eight Beans are laid on this, and covered over with 2 in. of the soil; this is also made firm, in order to prevent its becoming quickly dry. The pots are then placed in a house, where the heat is about 50° at night and 70° during the daytime. No water is given until the green leaves appear, then they are never allowed to become dry. Just before they come into flower they are top-dressed with a rich mixture, and at the same time twigs are put into each pot to support them when the Beans become heavy. Liquid manure is never given until the pods are visible. As one batch is exhausted another takes its place. Osborn's Forcing is the only kind we use for forcing; it is a compact-growing kind, and each pot will produce from six to eight dozen pods. Canadian Wonder, although excellent out-of-doors, grows too tall to cultivate under glass.—C.

Mushroom Culture without Manure.—It is not always that one can secure the horse manure and other necessaries to grow Mushrooms in the way recommended by some writers on Mushroom growing. This autumn I wanted to have some fine crops in a new Mushroom house which we have, but could not get any horse manure. I therefore collected a quantity of turfy soil, the result of thin cutting; with this I mixed a quantity of old, rotted straw and some green Grass, and threw the whole into a large heap, until it heated violently. It was then turned and well mixed, and, when still warm, was wheeled into the Mushroom house, beaten firm, and the spawn inserted in the usual way. The result is an excellent crop of good Mushrooms. When the crop seemed well-nigh exhausted, we dusted a sprinkling of salt over the bed, and watered it with tepid water, and shoals of fresh Mushrooms speedily made their appearance. Last year, among many makeshifts to secure Mushrooms, we used rotten sawdust mixed with a little horse manure, but with only moderate success. In the open ground tolerable crops were obtained late from heaps of soil mixed with Grass; but the best was from a quantity of manure very wet, in fact drenching, from a manure hill. This was placed 1 ft. thick, well beaten, and pieces of spawn inserted, wrapped in a good handful of hay. They were covered over with rich earth, and the crops were all that could be desired.—M. T. I.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

January 10.—Digging herbaceous border and among bedded Roses; sowing frame of early French Forcing Carrot intermixed with Radishes; also a little Incomparable Celery in heat; potting some standard Roses for next year's forcing; also some Broad Beans, placing them in Vinery, and a batch of Potatoes placed in slight heat; putting in Vine eyes; also cuttings of Purple King Verbena, Chrysanthemums, Alyssums, Salvia splendens, Heliotropes, and Fuchsias; throwing out trenches and filling them with manure on which to plant Seakale for forcing next season; planting Sweet Bays; throwing out holes in which to plant Pear and Nut trees after having trenched the ground; fumigating Gardenias and Calceolarias to keep down fly; turning manure in order to get it heated for Potato pits; pruning Roses on pillars.

Jan. 11.—Sowing more pots of Mignonette; potting Dendrobium Paxtoni and other Dendrobes in Moss and peat fibre; putting Epidendrum erubescens, Lælia majalis, and Disa grandiflora in a cold house to which air is freely admitted; putting cuttings of Salvia patens in heat; also putting in some Gooseberry and Currant cuttings; planting some Apple, Peach, Apricot, and Pear trees; also Raspberry canes.

Jan. 12.—Digging amongst bush fruits; sowing French Beans in pots and placing them in second Vinery; potting Nemophila and Saponaria for baskets; putting in cuttings of Gnaphalium lanatum, and also of Begonias; planting out Schizostylis coccinea; wheeling a portion of the rubbish-heap on to the Gooseberry quarter; making pegs in wet weather for flower beds; cleaning Onions.

Jan. 13.—Digging vacant ground; potting off autumn-struck Petunias; also Cucumbers, plunging them in pits, keeping them at 70°, and covering them at night; shifting autumn-struck Centaureas into 6-in. pots; striking cuttings of Lobelias in heat; also cuttings of Oxalis and Heliotrope; shifting herbaceous Calceolarias into larger pots; transplanting some Ghent Azaleas in order to prepare them for forcing; manuring Roses liberally; also any Plum trees that annually bear heavy crops, giving two barrow-loads to each. Turning the rubbish-heap in order to hasten decay so that it may be ready for use when wanted.

Jan. 14.—Digging borders in Rose garden; potting Veitch's Ashtop Potato for wall sides; also autumn-struck Fuchsias, and placing them in heat; plunging Fig trees, and starting house at 58° at night and 63° by day, fire-heat; putting in more Seakale and fourth crop of Rhubarb; still sending in Asparagus, Seakale, Mushrooms, Broccoli, and Spinach; putting seed Kidney Potatoes in hampers in loft, placing them end upwards and singly so as to get strong sprouts; putting ashes over Peas just coming up; pruning wall Roses, having finished those on trellises; planting some Winesour Plums.

Jan. 15.—Sowing Cyclamen seed; also Little Gem Peas under cases; taking offsets from Echeveria glauca and putting them into slight heat; potting Gladioli in two parts loam, one part manure, and one part peat and sand; putting Zygopetalum maxillare on Tree Fern stumps and placing them in a cool house; putting in cuttings of Tree Carnations; planting some Chives, Sorrel, and Royal Albert Rhubarb; Hyacinths coming into flower freely.

Glasshouses.

During the next three months Camellias will play an important part in greenhouses, especially where there is a sufficient number of plants proportionate in size to the dimensions of the house which they occupy. If these be arranged so as to act as a background to forced Azaleas, Cytisus racemosus, Epacrises, Correas, hardy shrubs, Cinerarias, Primulas, forced bulbs, standard Tree Mignonette, Salvias, Epiphyllum truncatum, &c., in combination with Agaves, Draceenas, Yuccas, Cordylines, Dasylirions, Lomatias, Phormium tenax, Tree Ferns, Cycads, and Macrozamias, a collective effect may be made not easily surpassed at any season of the year. Where a good supply, in small pots, of Lycopodium denticulatum, Isolepis gracilis, and Centaureas is at hand, they will be found most useful in hiding the larger pots.

Roof Climbers.—So far as these are concerned, there are few that, just at the present time, will contribute much by their display of flowers, but they should be all carefully gone over, and so far cut in as to prevent anything like crowding, or their spreading under the whole roof surface in a way that will too much exclude light. In securing them in their places, the practice of tying them in so tightly as to give the whole a stiff appearance should be avoided. On the contrary, a sufficient number of shoots should be left hanging in a pendent position to prevent this. Where insects of any description are troublesome, they should be thoroughly cleaned while the plants are comparatively in a dormant condition. For a like reason, and to enhance the general appearance, all the permanent occupants should, as often as time can be found, have their leaves sponged; this is the more necessary at this season when the syringe and garden engine are better not used.

Temperature and Air-giving.—The temperature of conservatories should be from 46° to 50° in the night, according to the weather, with a proportionate rise by day; this, as a matter of course, will necessitate an almost continuous use of fire-heat, to avoid the over-drying influence of which sufficient moisture must be given in the immediate vicinity of the pipes, otherwise the air will get so dry that its effects are certain not only to be seen in causing the unexpanded buds of Camellias to fall off, but it will also act injuriously upon other plants. Be very careful about the admission of air, even at such times as the sun happens to shine out clear and bright, giving it, as far as possible, at the roof. Much better let the thermometer rise considerably on the few occasions that it may be expected to do so for several weeks hence than admit a volume of cold air in direct contact with the plants.

Winter-flowering Heaths.—As soon as these have done blooming they should be at once cut back, so as to cause the principal shoots to break low enough to keep them from assuming the straggling condition they will get into if left to go on for another season without the last summer's growth being sufficiently reduced.

Primulas.—Both the single and double varieties should, where possible, be kept in a light house or pit, where they can be accommodated with a night temperature of from 45° to 50°, keeping them as close to the glass as circumstances will permit. The plants of the single varieties intended for later flowering should be some degrees cooler than this, and all must be watered with care, as if the footstalks of the leaves get much wet they will be liable to decay.

Cyclamens.—To grow these plants well they should be treated through the winter as to temperature much in the way recommended for Primulas, as, unless kept a little warmer than an ordinary greenhouse, they will not grow or flower anything like what they are capable of. Keep a good look-out that there are no aphides upon them, otherwise they get established in quantity on the young advancing bloom-stems without being noticed, in which case they will cause the flowers to come deformed.

Cinerarias.—If a sowing were made sufficiently early, and the plants have been well attended to through the season, they will naturally have come on into flower without anything above the usual greenhouse treatment, to which they should never be subjected, as even a very little heat injures them by destroying the under leaves and drawing the bloom-stems up thin and weakly, which spoils them for the general purposes of decoration, and if the flowers are wanted for cutting makes them comparatively worthless, as they flag directly. Keep the successional later-blooming plants as cool as possible, so that they are out of the reach of frost; by this means they may be had to flower in good condition up to the middle of May, during which period they will be found most useful, as they furnish shades of colour, especially blue, not only beautiful in themselves, but such as much enhance the effect produced by flowers of other colours with which they are associated, either in the conservatory or in a cut state.

Herbaceous Calceolarias. — Plants raised from seed sown last summer, and afterwards potted off singly, should at once be attended to by moving them into larger pots before their roots get at all confined, for if this occurs, the stunting influence will be such that they never afterwards can be induced to grow on freely, or to attain anything like the size and ability to produce such a quantity of flowers as when encouraged by liberal treatment. If, as may be supposed, they are occupying 3-in. pots, a portion may be moved into 4-in. ones or larger, in which they can be allowed to bloom. Those that are intended to have a second shift in addition to the present may be transferred at this time to 6-in. pots. They delight in rich, light soil, such as is composed of two parts good, free, turfy loam, with a third part consisting of equal proportions of leaf-mould and rotten manure, all mixed up with sufficient sand. In potting, avoid the extremes of leaving the soil so very loose as at one time was looked upon as conducive to their well-being, and also the opposite of compressing it in the pots to that degree of solidity necessary with Pelargoniums. The plants should have a light position in a pit or house that can be kept at a temperature of about 40° in the night, with a moister atmosphere than many plants require.

Shrubby Calceolarias intended for flowering in pots should be similarly treated; these do better with potting somewhat harder than the herbaceous species. Both should be from time to time examined to see that they are free from green fly. Where only a few individual plants amongst a number are affected, dipping in Tobacco water will prove an efficient means for the destruction of the insects, or they may be killed by fumigation, but where this is resorted to it will be safer to repeat it slightly several times than to subject the plants to a severe application, as they are much easier injured by Tobacco fumes than many subjects.

Show and Fancy Pelargoniums.—Plants of these that after being cut back were

shaken out and replaced in small pots, if not already transferred to those in which they are to bloom, should be attended to, as with them also any approach to a root-bound condition will stop growth and proportionately weaken their flowering capabilities; good turfy loam, of not too light a nature, well enriched with rotten manure and a little sand added, is necessary to grow these plants satisfactorily, and in potting, the soil can scarcely be made too solid by ramming it tightly in with the potting stick. When it is left too light there is always an inclination to run too much to leaf, with a comparative indisposition to flower. As soon as potted, they should at once be tied into shape, avoiding the over-formality consequent upon the unnatural trellis style of training sometimes resorted to, likewise that which leaves the branches with so little support that the plants cannot be moved when in flower to wherever required without the shoots falling about in a straggling unsightly manner. The fancy sorts, from their more sturdy growth, stand in less need of support, but both kinds should be trained sufficiently open to admit of plenty of light getting to the whole of the leaves, and to preserve a stout, bushy outline, which is their natural habit. Keep them, if possible, within a short distance of the glass in the lightest house available, and be careful for the next two months never to give water until the soil has got drier than it would be advisable to allow it in the case of most plants.

Chrysanthemums.—If cuttings of these are not put in, no time should be now lost. Choose shoots that are stout and strong, and have not be drawn up weakly, for, though the latter will root freely enough, they are a long time before they acquire strength. Do not put them in heat to induce them to root, as this has a direct tendency to cause top growth, which it is most desirable to avoid until roots are formed. They will strike easily, but slower inserted in a mixture of one-half loam and sand, covered with ordinary propagating glasses in a greenhouse temperature kept near the glass. It is advisable to see that they are free from aphides before putting them in. If the plants from which they are taken have been at all affected with these it will be better to dip the cuttings in Tobacco water previous to insertion.

Cool Orchids.—The house devoted to these should now be kept at from 38° to 45° in the night, and 5° or 6° higher by day, according to the weather. The principal plants to be considered in this department are the Odontoglossums and Masdevallias, both of which, but especially the latter, must never be submitted to drying treatment at the roots. The different other cool species that need total rest through the winter, during which time they require to be kept dry, may be treated in this way so far as will not entail much shrivelling, which is not likely to occur, as the atmosphere here will not be nearly so dry as that where more fire heat is used.

Flower Garden.

Now is the time for making new walks, and improving and renovating those already in existence. If the gravel be discoloured or Moss-grown, break it up with forks, and leave it loose until rain has fallen; then rake it over and roll it down, when the walk will look as if fresh gravelled. Walks under the shade of trees and shrubs where there is no Grass to be killed need not be broken up, as a sprinkling of salt will both kill the Moss and give brightness to the gravel; but for use in open spaces salt is not to be commended, as, even with the greatest care, it frequently kills the Grass verges, and after a time it acts as a manure, and increases rather than diminishes weed growth. Levelling turf and relaying it should be forwarded as fast as the weather permits; also all grubbing, trenching, and alteration. The shrubbery borders may now have their annual pointing over, an operation which is necessary, not so much for the benefit of the shrubs as for the removal of weeds and the fixing of blowing leaves. Herbaceous borders are now looking weedy, and where, as is usually the case, such borders contain large clumps of bulbous plants, not much can be done to improve matters till these show themselves above ground, but as soon as they do so, contemplated rearrangement and division of the plants may be proceeded with, and the borders may be manured and dug as deeply as the occupants will permit. If the weather be open and favourable, the sooner all intended planting of Roses is completed the better. Standards and others requiring support should be staked at once, to prevent injury from high winds, and the beds should be mulched as before recommended. Beds of Anemones, Ranunculuses, and choice Hyacinths and Tulips that are peeping above ground will be all the better for a covering of Spruce or Laurel boughs laid thickly over them. Echeverias have suffered severely, and the reserve stock must be looked to, in order to see that no losses occur amongst them. All other bedding plants, more particularly those required in quantity, must be examined, and tender kinds introduced into heat for the production of cuttings. See that roots of Dahlias and Cannas are secure from all danger from frost; the middle of February is sufficiently early to introduce them into heat.

Carnations and Picotees.—Ventilate frames in which these are growing freely, but let no rain fall upon the leaves. Raise the lights by tilting them on blocks, and in fine weather remove them. If there be any traces of aphides on the leaves, fumigate on calm nights until they are destroyed. A pair of sharp-pointed scissors is useful to cut off portions of decayed leaves. Plants in beds must be looked over occasionally, and those not steady in the ground must be made firm by pressing round the base of the plants, and a neat stick should be placed to each in order to prevent any injury from high winds.

Single-flowered Japan Pink (Dianthus Heddewigi) (See next page.)

Dahlias.—The roots of these are sometimes injured by being stored in unsuitable places, such as those that are either close and damp or too dry. It is well, therefore, to examine them carefully. Close, damp sheds with a northern exposure do not answer. If the roots are not keeping well, look over them, remove decayed portions, and place them in boxes in dry mould, removing the boxes to a Vinery, Peach house, or other structure from which frost is excluded.

Hollyhocks.—All decayed leaves and portions of leaves should be removed, and air should be given on all favourable occasions, excluding damp. In foggy or close, wet weather it is best to keep the lights closed; mould soon gathers on decayed portions and must be looked after. Plants in pots in houses from which frost is excluded are not likely to suffer any injury; they must not, however, be allowed to become over-dry at the roots.

Pansies.—Favourable weather should be taken advantage of to pot such plants as are intended for pot culture; 6-in., 7-in., or 8-in. pots answer best, and either one of these sizes may be used, according to convenience. One plant, if large enough, will be sufficient for a pot, but small plants may be utilised by placing two or three in each pot. The soil ought to consist of about four parts turfy loam, one rotten manure, one leaf-mould, and one sharp sand. Press the mould in firmly with the fingers round the roots of the plants, and see that plenty of drainage is placed in the bottom of the pots.

Fruit.

Vines.—In mid-season houses, as soon as the fruit is cut, forthwith prune the Vines and they will go more effectually to rest. Indeed, to do them justice, all Grapes should now be cut and put in bottles of water; they will keep better if cut now than if left on the Vines another month. Any dry room in which a temperature can be kept above 40° is suitable for the purpose, and as much wood as possible, both behind and in front of the bunch, should be cut along with it to act as a deterrent to an overplus of moisture being communicated to the fruit.

Peaches.—Prune the trees in late houses; wash or paint them over, as a preventive against insects, with soap-suds, Tobacco water, and sulphur, made to the consistency of thin paint by adding clay or cow manure to cause adhesiveness. This done, top-dress the borders by removing all the loose, inert top soil, and replacing it with good loam, a little bone-dust, wood-ashes, or pounded charcoal. Peach borders in either early or late houses should never be allowed to get dry, and if the drainage be good and there be a free outlet, there need never be any fear of the borders getting too wet. New borders in course of formation should be completed as soon as possible, as it is quite time the trees were planted if good growth be desired this season. A good Peach-producing soil should consist of loam of medium texture, rather stiff than light, chalk or lime scraps, and charcoal. Manure, if required, is best applied in a liquid state when the trees are in full vigour.

Melons.—For fruit required early in May sow at once, and, in order that they may germinate kindly, they will require a bottom-heat of 80°. The seeds should be put in pairs in 3-in. pots, and when up, the weakest plants should be destroyed. When sown, as is frequently the case, a number of seeds together, the check caused by division is considerable. Grow the plants as near the glass and with as much light as possible.

Vegetables.

Plant Cabbage out according to demand from the store beds of the autumn sowings, and sow a sprinkling of some small early sort in a frame or in a warm border. Examine the stored roots of Carrots, and remove all decaying ones, from which cut away the decaying portion, and use the wholesome part at once. Sow a few Early Horn Carrot seeds on a slight bottom-heat. Sow Cauliflower seeds in frames in a very gentle heat. Freely expose on every favourable opportunity those wintered in frames, and tilt up the sashes at back and front during rainy weather.

Sow Celery seeds in pans of light rich soil in gentle heat. In case of hard frost, protect the Celery in ridges with litter or Fern. Lift the old plantations of Horse Radish, and store the roots in sand in a pit or cellar, but every particle of the roots, small and large, should be removed from the soil. Make fresh plantations in deeply trenched ground. Sow some seeds of the white and green Paris Cos Lettuces in frames, and the Bath Cos in rows where they are to remain. Draw the lights off the frames containing late autumn sowings in favourable weather. If a frame can be spared for the purpose, sow some Tripoli or white silver-skinned Onions for salading, as they will come in six weeks sooner than the main outdoor sowings; and what are not required for this purpose can be transplanted in the open ground.

Peas.—For the first sowing of Peas, the driest portion of ground at command should be selected; the soil may be drawn in ridges about 8 in. high, flat at the top, and 12 in. broad; they should be made by drawing as much of the soil from the whole surface of the bed as will form these ridges at a distance of 3½ ft. apart for such varieties as William the First or Sangster's Number One. Sow on the top of the ridges, covering with about 3 in. of any sandy, open material, such as old potting soil, covered with 1 in. of ashes; or if this be not at hand, the ordinary garden soil, mixed with one-third of its bulk of sifted coal-ashes, is a good substitute. As a precaution against mice, coat the Peas with red lead, or lay under the covering of soil 1 in. of Gorse chopped fine on the top of them. It is advisable to sow thickly at this early season; a quart of early kinds will be found sufficient for a row about 18 yards in length. If the situation be at all exposed, as soon as the Peas appear above ground, take as much more soil from between the rows as will form a ridge on each side of the Peas high enough to break the force of the wind. Do not tread on the land more than can be avoided. Should the ground have been dug early in the autumn, such crops as the above may be put in without trampling upon the soil at all by simply using a few boards about 10 in. or 12 in. wide that will reach across the bed; the little extra labour involved in their use will be amply repaid in the produce.

Broad Beans, where required early, should also now be sown. If the land be at all inclined to be wet, sow on the surface and cover as recommended for Peas, in which way it is evident the seed will be much better able to resist the effects of the excessive moist condition of the soil. In heavy, retentive ground, and in localities where the spring is backward, it is far preferable to defer sowing for at least a month.

Potatoes.—The earliest sorts of Potatoes should now be placed in single layers in shallow boxes, in a place where they will receive sufficient light to cause the sprouts to grow stout and strong. The best varieties for general cultivation are the Ashleaf Kidneys. Of Round Early Frame kinds, Handsworth and Early Oxford are among the best. The boxes in which the tubers are placed should be protected from frost.

Lilium lancifolium.—Some time last year I sent you an account of some Lilies (Lilium lancifolium) which I had grown in a box without disturbing the bulbs. I stated that in the beginning 1878 I planted six bulbs in a box, which was of an oblong shape, being 8 in. wide, 10 in. long, and 14 in. deep, and that these bulbs threw up six stems, bearing altogether 24 flowers, in the autumn of that year. After the stems had died down, the box was placed in the summer-house for the winter. In the spring, when the Lilies had shown themselves well above the soil, the box was put in its place for the summer. The plants were watered with weak guano water up to the time of flowering. This year (1879) thirteen stems were thrown up, producing 87 flowers. The box was put away as before, but in the spring of the present year the bulbs, with the earth disturbed as little as possible, were shifted into a larger box, this one being about 18 in. square by 24 in. deep. Soon after shifting, the bulbs threw up 26 stems, which bore 229 flowers. Two of the stems had 16 flowers on each of them, three had 14, two had 13, two had 12, the rest having from 1 to 11 on the stem, those having only one bloom on being very small. The plants were watered with guano water (½ oz. of guano to a gallon of water) three times a week from the time of their being 6 in. high until they flowered. After the plants have flowered they should not be left to take care of themselves, for while the leaf continues in a healthy state it is elaborating sap for the nourishment of the bulb; and therefore the longer you can keep the leaves healthy, the better will your chance for flowers be the following year. Those readers of GARDENING who had Gladioli in their gardens last summer might have noticed when taking up the bulbs, or corms, that the plants whose leaves had died early in the season—a thing which often happens to Gladioli—had formed very small corms; while those whose leaves had remained healthy until after the flowers were over, produced fine healthy corms of a good size, thus showing that it is the leaves which form the bulbs of plants.—S. D. SAUNDERS.

FLOWER SEEDS FOR THE COMING SPRING.

THE catalogues of some of the large seed houses having just reached us, we have made a selection of plants from those of Messrs. Sutton & Sons and Messrs, Carter & Co., which are worthy the notice of our readers. They may be all raised from seed sown in the open ground in March, and will give a good display during summer.

Cut-flowered Japan Pink (Dianthus laciniatus).

Double Japan Pink (Dianthus diadematus).

Dianthus Heddewigi, D. H. laciniatus, and D. H. diadematus.—These are greatly improved strains of the Japan Pink (Dianthus chinensis), and are among the most attractive of annuals. The flowers are of the richest colours, and of great value for cutting for bouquets or vases. A cultural article on these Pinks was given in GARDENING, Dec. 25 last, p. 511.

New Everlasting (Helichrysum Fireball).—This is a double crimson-flowered kind raised in Messrs. Carter & Co.'s seed grounds. Most of the Helichrysums are but dull in colour, therefore this will be an acquisition. An article on the culture of Everlastings appeared in GARDENING on p. 497, Dec. 18.

Eschscholtzia Mandarin.—An easily-grown annual and one of the most showy. Its flowers are of a rich orange colour inside, the outer petals being brilliant scarlet. When seen in masses this is a remarkably showy plant. Its flowers last for some time in water.

GROWING ARUM LILIES (CALLAS) IN WATER.

SEVERAL remarks lately made in GARDENING remind me of a system which I once adopted of growing this plant as an aquatic in the open air. When well grown, this Arum is a grand plant whether in flower or not, its fine leathery leaves giving it a truly tropical appearance, but as generally grown it gets drawn or leggy, and, except when placed amongst other plants, it is

not always what would be called a good habited plant. It is truly noble when grown in groups or masses, a condition, however, in which it is seldom or never seen. To accomplish this, the following plan may be adopted: This Arum is well known to be half-hardy and semi-aquatic; therefore select some sheltered nook on the lawn for it; if near a shrubbery in a recess, so much the better. Towards the middle of May collect your plants, twelve, twenty, or thirty, as the case may be; go to the brewhouse and procure one of those large, shallow vessels known as coolers. These are either round or oval, and would hold, according to size, from twelve to thirty of the plants. Carry

Crimson Eschscholtzia (E. Mandarin).

the cooler to the spot selected, and place it in such a position as when filled with plants it would appear to the best advantage. When *in situ*, mark out on the Grass the space occupied by the cooler, remove it, and then remove the soil from the inside of the marked space to such a depth that when the vessel is placed in it its rim shall be about 6 in. below the surface; clear all your excavated material away. Group your plants in the cooler as you would arrange a bed of shrubs, the strongest and tallest being in the centre; fill the cooler so that the pots may stand in about half their depths in water. If the cooler should be old and leaky, puddle it outside with clay. Procure some thin strips of wood (stout wire will do as well), and introduce them between the plants tolerably close together, crossing them if necessary; tack down these strips to the edge of the extemporised tank. The plants will now appear to be growing in water through a trellis. Procure a quantity of Moss, in as large pieces as possible; lay this evenly on the wire or strips of wood all over among the plants, bringing it out so that it may appear part of the natural turf. You will now have a group of Arums growing in water, but apparently growing out of the turf, and the proximity of the Moss to the water will keep it always fresh and green. Plants thus treated will present a grandeur rarely seen when grown in the usual way, and it is highly probable that treated in this manner in many localities they would survive the winter. T. W.

CULTURE OF TRITONIA AUREA.

FEW bulbs are more easily managed, or more easily lost by mismanagement, than this. The bulbs should be bought as soon as they can be got, and should be out of the ground as short a time as possible. They may be planted 3 in. or 4 in. deep, in pots or boxes, in any soil, a mixture of sandy peat and light, fibrous loam suiting them best. They may be placed anywhere out of the reach of frost, but the less they grow during winter the better. They must, however, be watered at once, and the soil must never be allowed to get dry. This is the most important point in their treatment. They succeed well as border plants in any soil except clay, but seem to like moist beds of peat soil best; they may be planted out in April or May. I have had the shoots killed to the ground by frost in May without injury to the bulb, though of course the growth was weakened and retarded. Treated as a cold frame bulb, and planted out, they will flower in the south in August, but in the north of England a month later, and in cold places it is better to bring them on for a longer time under glass and plant them out later, or to treat them altogether as greenhouse bulbs, for which they are well suited.

Though tolerably hardy, there are two objections, besides the lateness of their flowering, to leaving them out all winter in the open ground—one, that they are liable to be killed in severe winters unless well protected with litter; the other, that, owing to their habit of straying, in which they much resemble Lilies of the Valley, they are apt to leave the place in which they were planted, and come up where they are not wanted. It is better, therefore, to lift the whole stock in autumn; and as they may, if necessary, be potted many together, and separated when planting-out time comes, this takes little trouble or room. I lift mine about the beginning of November. This must be done carefully; for although the tops are not yet dead, the shoots which form the new bulbs next year are already several inches long, sometimes even more than 1 ft. These shoots are jointed suckers, not unlike those of Couch Grass, and as soon as they have completed their horizontal growth, the nucleus of a new bulb is formed on the last joint. This young bulb then makes roots, and sends a shoot perpendicularly upwards to become the flowering-stalk of next year. I have not ascertained the exact time at which the parent bulb ceases to be necessary or useful to its offspring, but I believe it to be soon after the young shoot appears above ground. The sucker connecting the new bulb with the old gradually dries up into a hard, wiry thread.

When the bulbs are lifted in November for replanting, if sufficient care be taken, the last year's bulbs will be found—to outward appearance, alive and sound, like the old corms of Gladioli—connected with the new bulbs by these threads. If the shoots of the bulb have once been made, and been broken off, or allowed to dry up, no treatment will make it produce another shoot. The old bulbs can readily be distinguished by having no stalks or shoots, and may be pulled off and thrown away. It will be understood after what has been written above that anything like drying off or storing the roots in a dry place is fatal. They had better not be left uncovered for a single day. When the suckers dry up they die, and the bulb, though continuing sound in appearance, dies with them. Care must also be taken in potting to keep the long suckers at the same depth as the bulb, turning them round the inside of the pot, for if the points are brought above ground before they have completed their horizontal growth and commenced the formation of a bulb, the suckers die. When planted they must be carefully and repeatedly watered. The shoots on appearing above ground will probably all be found to touch the edge of the pot; hence, if you can spare say a 4½-in. pot for every two or three bulbs, they are in the most convenient condition for planting out again with a ball of soil when the time comes. C. W. D.

Late-blooming Antirrhinums.—Plants of these hardy biennials in a large bed, cut over in October in order to secure a crop of seed, throw up large numbers of side shoots, and which yielded an abundance of richly-coloured flowers. How useful these are at a time when there is little else in bloom out-of-doors those can best estimate who have to find flowers somehow, and who are only too glad to have any useful plant from which to cut. The plants in question were from seeds sown indoors early in spring, the seedling plants being pricked out into boxes until strong enough to be planted out in rows in the open ground. These dwarf kinds produce a much larger proportion of striped and fancy-coloured flowers than is usually found in the tall strains, and the bed, when in full bloom, was indeed worthy of admiration. What a beautiful mass of bloom may in this way be had at the cost of a few pence for a packet of seed, and if merely wanted for cutting, the plants might be grown in any out-of-the-way place for that purpose.—D.

HOW TO GROW THE HYDRANGEA.

APART from its interest as a pot plant, the Hydrangea has considerable claims upon our attention as a shrubbery-border plant, and seen, as we sometimes find it, in favourable spots upon the sea-coast, it is certainly one of our most effective deciduous shrubs. In Devonshire and Cornwall, South Wales, more especially near Swansea, North Wales, Anglesey, and some other districts, we have frequently met with specimens of the Hydrangea growing in the open ground, huge bushes 6 ft. and 8 ft. in height, and quite as much in diameter, each producing scores, perhaps hundreds, of trusses of its gorgeous flowers, sometimes pink, and in other cases a soft cœrulean blue. Where, indeed, a soil is strongly impregnated with iron, whether it be loam, peat, or sand, you may almost make sure of blue flowers being produced.

Soil.—The Hydrangea is a plant which, to grow it to perfection, does not need a compost, that is, there is nothing gained, but rather the contrary, by compounding a soil for it. I have spoken of loam, peat, and sand; the two former of these will suit the plant perfectly in the simple form, and, indeed, much better than when mixed together. For choice, however, I prefer a nice mellow loam, not too light, and in that, with occasional waterings of liquid manure, the plant will grow in the most perfect manner. The fashionable soil, especially for producing blue flowers, when I practised near London, was the Norwood loam. That was rather strong, and parts of it full of red streaks of iron rust, but when broken down and exposed to the weather for a few weeks it formed a fine potting soil, and one in which the plant delighted.

Propagating.—The Hydrangea may be very readily propagated by cuttings, and those which are taken from near the base form the best plants. My own rule used to be to put the first batch of plants into the forcing-house about Christmas time, and those, if the temperature was growing, gave some nice cuttings before the end of January. These were taken off when not exceeding 1 in. in length, and were put in propagating pots in the usual manner, the only precaution taken being to surround the

Crimson Everlasting (Helichrysum Fireball).

base of the cutting with some sharp sand The temperature of a Cucumber frame is the most suitable for striking this plant, always observing the good old rule never to allow the cuttings to droop until the roots are formed.

Potting and Temperature.—Directly the cuttings are nicely rooted pot them off, using the soil you intend to continue; put them into small pots first, and when those are full of roots remove them to the size in which it is intended that the plant shall bloom. A few of

the strongest may require 6-in. pots, but as a general rule the 4-in. size will be found sufficiently large for the first season. The temperature for the plants must be brisk, moist, and growing, and care should be taken that the plants be kept near the glass, so that they may make thick, sturdy, healthy growth, the stem not being more than a few inches in height, and each leaf nearly as large as your hand. Ripen such a growth thoroughly, get the leading bud nearly as large as the end of your thumb by the time the leaves begin to fall in the autumn, and then you may make sure of a grand panicle of flowers the following season. To effect this kind of growth a frame or pit is most desirable, especially in the early part of the season, and where that cannot be secured put the plants upon a shelf near the glass, and as they are greedy feeders, place each pot in a feeding saucer, so that water may be put in if necessary.

Hardening off and Wintering.—When the growth is made, gradually inure the plants to the open air, so that by the end of May they may be set under a south wall to get thoroughly matured, and then be removed to a more shady situation to pass the season of rest. Keep the plants comparatively dry when the leaves begin to ripen and fall off, but do not attempt to force a premature ripening by withholding water before the plants give indication that the season of maturation has arrived. The best place to winter the plants will be a dry, airy shelf, and but very little water will be necessary. This completes the first season's management.

Second Year's Management.—In the second year, if flowers are wanted early, say in April or May, forcing must commence at the end of December, and be continued in the temperature of the early Vinery until the flowers begin to show colour, when the plants may be removed to a cooler atmosphere. There is no advantage in potting the plants before they bloom, as they seldom make root in the fresh soil; but each pot may have a feeder containing water placed under it, which may be kept filled during the sunny hours of the day, but at night they will be better empty. When the planks break, reduce the side shoots to three or four of the best placed upon each plant, which may be grown on for future blooming, and the others may be used as cuttings. If particularly large individual flowers are required, thin out, directly they are fully recognisable, half the buds upon each truss, of course choosing the weakest and worst placed. The truss of a well-grown Hydrangea should be at the least a foot or more in diameter, and each flower should be nearly as large as a five-shilling piece. Thus grown, the Hydrangea, whether blue or pink, is a very imposing object, and will remain in perfection in the conservatory for two months.

Treatment after Flowering.—Directly the bloom becomes faded cut the branch away to the secondary shoots, which are to form the blooming shoots for the following season. These must receive all the encouragement that can be given them, and for that purpose it will be necessary to shift the strongest plants into 8-in. pots and the others into pots one size smaller. Use the same kind of soil, and, at the time of shifting, remove the crocks, and at the same time, with a pointed stick, loosen the matted roots around the ball, so as to induce them to root into the fresh soil. Of course, after this shifting, the plants will require to be kept close and shaded until they make fresh roots, and then they must receive just the same encouragement they did in the first season. These plants, if properly grown and ripened, will in the following season produce three or four fine trusses each, and then form very handsome subjects for vases. If it is desired to grow the plants a third year, the same process as to disbudding must be followed, and then a dozen shoots to each plant may be encouraged. I generally, after the second season's blooming, put the plants in the open ground, mixing them in the borders with the American plants, where, in August and September, they form very effective objects.

In Beds and on Lawns.—For early beds in the dressed flower garden the Hydrangea is very desirable. Plants started in January come into flower in April, and form very nice groups through May and June. For single specimens upon the lawn, in places where the wood ripens properly, the Hydrangea forms a very fine object; where it does not ripen, large specimens should be grown in pots or boxes, and be set out upon the terraces in the summer season. They form capital companion plants to the scarlet Pelargoniums. When grown in permanent beds, the soil should be porous and well drained, and should be raised well above the general level of the surrounding soil. Hydrangea hortensis and its variety with the variegated foliage are the kinds most generally grown, the latter especially for its foliage. A few plants of H. japonica may also be cultivated, but they are not so effective as the older species. Those who require blue flowers speedily may crush some alum into fine powder and put a pinch occasionally upon the surface of the soil. This will give blue flowers, but it will be at the expense of the health of the plant, which must be thrown away when it has done blooming.

W. A.

TRAINING APPLE TREES.

YOUR clear illustration of improved espalier fruit tree training on a 10-ft. trellis for cordon Apple trees, given in GARDENING, Dec. 4, affords me an excellent hint, in the direction to which I have recently turned my thoughts. At Bangalore the patient and skilful gardeners grow fairly good Apples all the year round, but about this time, or a little later on, they produce well-flavoured fruit of such size and shape that would not discredit a country show here. But then they ask and get Christmas prices, say 10s. to 15s. a dozen, and occasionally more. They grow them on upright scanty bushes, about 6 ft. high (whose very shape suggests the espalier treatment), for the convenience of picking and pruning. They protect the growing fruit very carefully, tying them up to ease the weight, so that when ripe an Apple often appears rosy red, and variegated with three or four yellow stripes where the sun has been excluded by the slings. They pinch, train, and root prune with much skill, and my object is to aid in promoting a more extended culture in the direction of greater variety, finer fruit, and, what is a great matter (and a natural sequence), reduced price. When reading the article on American Apples in the *Daily Telegraph* of December 3 my ideas at once went back to the Lal Bagh and the Apple gardeners of Bangalore, and by the last mail I sent to Mr. J. Cameron, the superintendent of the Government Gardens, your issue of December 4, with some notes on the subject, adding that I had no doubt that the upright espalier trellis would at once find acceptance with the native gardeners, who are so ready to adopt any plan that commends itself to their keen judgment and skilful industry, as, in point of fact, it would be only gently leading them on in their present mode of culture. I saw Colonel Johnson at the club on Saturday, and told him of this. He has now, as secretary to the Local Government in Mysore, in the Department of Public Works, charge of the Lal Bagh, and we talked over the subject *con amore*, for he is well known as an amateur gardener and grower of fine Roses. He returns there by the next mail, and promised to see that the plan is fairly tried, and will aid the superintendent in what he, I am sure, will also enter into *con amore*. The sketch at page 471 and the details at page 473 are all that is necessary to enable a fair trial to be made, from which I expect excellent results. In the meantime perhaps you or some of your numerous readers might be tempted to give me a list of American varieties from a kindred climate that would succeed in our fine climate of Bangalore, where the mean temperature in shade is 75° for the year, the maximum 93°, and the minimum 57°, over a series of ten years, and where, with "shelter without shade," Mr. D. T. Fish's excellent motto for the Rose grower, in which, from long experience, I most thoroughly concur, and judicious irrigation, almost anything will grow. Bangalore, the garden of South India, is on a plateau of 3000 ft. above the sea, with a sub-tropical climate, and possesses peculiar advantages in having a semi-Alpine climate close at hand (20 hours by rail), at Coonoor and Ootakamund, 6000 ft. and 7000 ft. respectively, where hedges of Fuchsias, and Geraniums, and tree Rhododendrons, &c., are common. An intermediate climate on the little plateau of Nandidroog, 4800 ft. above the sea, close at hand for seed renewals and so forth, and Madras, where the foliage plants, particularly the Acalyphas, Crotons, &c., are magnificent, within 12 hours. As the Orientals say, "What more can I say?"

J. P.

OLD SEEDS.

LAST autumn a friend of mine gave me some seeds of flowers, which he had had since 1874. He said that I might as well give them a trial, although he did not think they would come up very freely. The seeds were sown either in pots in a cold frame or in slight heat. Those seeds which have an asterisk against them were sown in heat. The following is the result of my trial:—

Seed of 1874.

Name of Plant.	When sown.	Came up.	Flowered.
Dickson's Golden Gem Pansy	April 7.	—	—
Viola Admiration	April 7.	—	—
Viola striata	April 7.	—	—
* Balsam	April 9.	April 19.	July 22.
* French Marigold	April 9.	April 17.	June 29.
* Mimulus	April 9.	April 19.	June 20.
Mimulus	April 9. (In one of Looker's patent boxes in a cold frame.)	April 22.	June 16.
* Clematis lanuginosa	April 9.	—	—

It will thus be seen that the Viola and Clematis seed did not germinate, although the greater part of the seed of the Violas was sowed in boxes in a cold frame; still, a small amount was placed in heat, but with the same result. The Balsams did very well, while the Mimulus were first class. The Marigolds did not flower so freely as I have seen them when grown from seed not so old.

I have kept an account also of the time of planting some Gladioli, and of some seed which I bought last year. The following is the result:—

Name.	When sown or planted.	Came up.	Flowered.
Light Gladioli	March 26.	May 3.	August 22.
Light red Gladioli	March 26.	May 15.	August 28.
Gladioli gandavensis	March 31.	May 8.	August 27.
Phlox Drummondi	April 12.	April 24.	July 15.
Linum grandiflorum	April 13.	May 4.	July 8.
Nemophila insignis	April 13.	Apri 23.	June 18.
Minor Convolvuli	April 13.	April 22.	July 3.
Major Convolvuli	April 19.	May 26.	August 25
* African Marigold	April 22.	April 25.	August 22.
Candytuft	May 1.	May 16.	July 6.
Mignonette	May 1.	May 16.	July 8.

Of course these results might have been influenced by weather or locality; still, to those of your readers who wish to have flowers in bloom at a particular time the above notes may be useful. I will add that, with exception of those sown in heat, all the plants were raised in a cold frame and planted out when large enough. Those in heat were removed to the cold frame when they had four leaves, exclusive of the seed leaves, and after having been gradually hardened were planted out.

S. D. SAUNDERS.

ANSWERS TO QUERIES.

3965.—Maggot on Cabbage.—If the soil will bear it, trench it up 2 ft. deep, burying the exhausted soil in the bottom of the trench. Leave the surface rough through the winter, and in February give a dressing of manure, and, in addition, about a bushel of soot and lime per rod would be very beneficial, and if the soil is of a porous nature 20 pounds of salt per rod might be added with advantage, forking it in and well working the land when the surface is dry to obtain a fine tilth before cropping.—E. H.

3967.—Weeds on Lawns.—Something depends upon what kinds of weeds are mixed with the Grasses in the lawns. If they are Plantains or others difficult to eradicate, it will be cheaper to dig up clean and re-sow Grass seeds of good quality from a first-class house. There is not much chance of getting rid of weeds by simply raking with an iron rake, but if the weeds are of ordinary kinds, such as Chickweed, Groundsel, Shepherd's Purse, &c., then raking and hand weeding together may be trusted to keep them under till, by top-dressing and sow-

ing new Grass and Clover seeds in spring, a good growth could be obtained to smother the weeds. Sow plenty of Grass seeds, covering them with the top-dressing.—E. H.

3973.—**White Worms in Soil.**—The best thing to do with the Maiden-hair Fern will be to turn the plant out of the pot, shake away the loose soil, and then with a pail of chilled water wash the roots of the plant, cleansing it thoroughly. Then, when the water has drained away, re-pot in a clean pot, well drained, using sweet fibrous peat and silver sand. A bit or two of rough loam or a handful of finely-broken charcoal will be no disadvantage. Do not give much water till the new growth breaks away.—E. H.

3969.—**Cropping a Garden.**—Unless the Potatoes are of the very short-topped kinds, 2 ft. will be too close. Better plant at least 3 ft. apart if Brussels Sprouts are planted between the rows, as there is nothing gained by overcrowding; rather the reverse. Fifty pounds in weight of guano may be profitably used on fifteen rods of land; better use it as a top-dressing after the Potatoes are up in spring and hoe it in. Soot, also, will be beneficial used in the same manner. Brine from a bacon-curer's will be a good application to porous soil, but should be largely diluted with water. Apply it in spring just before cropping.—E. H.

3961.—**Scale on Vines.**—Add a wine-glassful of paraffin oil to a gallon of liquid in which 6 oz. of Gishurst Compound has been dissolved. Take some pains to mix it thoroughly; then add as much clay, lime, and soot as will bring the mixture to the consistency of paint. Apply it cool with a painter's brush, rubbing it well into the cracks. Of paraffin alone two tablespoonfuls to a pint of water applied with a sponge will kill scale on Vines. Some pains must be taken in mixing.—E.

3974. — **Rhododendrons.** — Rhododendrons: Early-flowering varieties—Sir W. Scott, Albertus, Altaclarense, Jacksoni, Mars, Florence Nightingale, Blandyanum, Beauty of Surrey, Delicatissimum, Faust, Lady Gordon, Iago, Ne Plus Ultra, Pictum, Ingrami, Ornatum, Sir C. Napier. Late varieties—Candidissimum maculatum nigrum superbum, Vandyck, Mr. John Waterer, Mrs. John Waterer, Mrs. Standish, Star of England, Standish's Perfection. If commoner kinds are required plant the varieties of ponticum. Though Rhododendrons grow best in deep peaty or alluvial soil, yet they may be planted in almost any soil that is deep and rich, and free from lime, and not too much exposed to cutting winds.—E. H.

3981.—**Hastening the Decomposition of Manure.**—We can advise no better method of hastening the decomposition of stable manure than is adopted in the making up of a hotbed. Shake it well up, moisten it well, and turn it often. In this way none of the ammoniacal properties of the manure are lost, nor is any driven out by fermentation or dry heating. A regular turning of a heap every two days for a fortnight, and water added often enough to keep down fermentation, causes every portion of the manure to become equally nutritive and in the best possible condition for application. There is waste when manure is applied in a complete state of decomposition, because that process is brought about by fermentation, and that means evaporation of the manurial gases. It is worse than waste; it is almost useless to apply the manure when it has heated itself, fire gauged or hot dry. Without fermentation and in a raw fresh state is, if less wasteful, at least not so readily assimilated as when it is prepared by frequent turning.

3983.—**Best Show Chrysanthemums.**—In giving the names of twelve show Chrysanthemums the querist does not specify whether they are to be solely incurved kinds, or solely Japanese, or a mixture of both. As, however, the term "show" is most commonly given to the large incurved kinds, we give the following selection as a good one: Beethoven, Empress of India, Dr. Sharpe, Golden Beverley, Jardin des Plantes, Prince Alfred, Prince of Wales, Venus, Hero of Stoke Newington, Alfred Salter, Barbara, and White Venus. These make a fine dozen to furnish cut flowers. If wanted for plants, Mrs. Haliburton, Lady Hardinge, Mrs. G. Rundle, Mr G. Glenny, and General Bainbrigge may be substituted for some of the others. Twelve good Japanese kinds to furnish cut show blooms are, Elaine, Fair Maid of Guernsey, Peter the Great, Fulton, Fulgore, Bouquet Fait, James Salter, Baronne de Prailly, Meg Merriles, Triomphe du Nord, Soleil Levant, and Cri Kang.—A. D.

3962.—**New Potatoes.**—It is difficult to give a complete list of all the new Potatoes that came out in 1880, because the knowledge of some does not get far beyond the lists in which their names appear, therefore we can but name those well known. Matchless is a new American, skin pink, tubers flattish, handsome, and smooth, quality medium, and haulm spreading and robust. Pride of America is very like Snowflake all round, but gives generally handsome tubers. St. Patrick a sort very like Magnum Bonum, but the tubers have deeper eyes. Reading Abbey, tubers much like those of Victoria, and similar quality, haulm very tall and robust. Heather Bell, kidney-shaped tubers, white skin mottled with purple, good quality, haulm very spreading and robust. Ice Cream, long white kidney of good quality, haulm medium height. Avalanche, handsome white kidney of high quality, robust haulm. Holborn Favourite, a pretty pink-skinned oval-round, of good quality and has a robust top; and Beauty of Kent, a bright red round, of excellent quality and having a moderately robust haulm. These are all the kinds we can at present call to mind as sent out during the past year.

3972.—**Pruning Clematis.**—The pruning of the Clematis is guided by the section to which the variety to be pruned may belong to. Thus all the spring-blooming kinds flower from the previous year's wood, and therefore in good pruning the strongest growths of the preceding year must be retained and the rest taken out. Still, it would be well with these to shorten back each shoot moderately, as the extreme growth is rarely firm and ripe. In performing this pruning and thinning it is well to unnail the entire plant, and then renail only that to be retained. The autumn-blooming kinds, viz., those that bloom from July onwards, all flower from wood of the present year's growth, and this should be cut back quite hard without compunction, say to within 2 ft. of the ground, every winter. Then new and very strong growth, producing the finest flowers, comes up in the spring and bears bloom profusely in the autumn. Your plant would seem to have got into an overgrown state that renders it difficult to deal with, and it would seem you can do nothing better than thin out carefully, and to the best of your judgment.—A. D.

3975.—**Pancratium carribbæum.**—The Pancratium carribbæum is a stove bulb, somewhat similar in constitution and habit to the Eucharis amazonica. It requires a time of growth with plenty of moisture, then a time of rest with less water, but should never be altogether dried off. The soil should be rich and fibrous in character, and the pots well drained. Most of the failures in bulb culture arise from a mistaken notion that bulbs do not require light and sunshine.—E.

3971.—**Melons and Figs.**—Both Melons and Figs may be grown in pots in the same house with care. Start the Figs first, and when they have made some progress, so as to require a night temperature of 55° or so, introduce the Melons. The latter should, if possible, have a little bottom heat. Could the pots be arranged over the pipes in some way? The Melons of course must be trained near the glass, say within 16 in. If they are trained thinly the Figs may stand under them. Great care must be used in regulating the ventilation and moisture; if the red spider once gets a footing in the house all will be ruined.—E. H.

3960.—**India-rubber Plants.**—India-rubber plants are very suitable for room decoration, but at this season of the year they must have all the light possible, and not be over-watered. It should be borne in mind that no plants—not even the most long suffering—will continue in health in a room where much gas is burned. Place the plant in the lightest position of the room during the day, and move it at night if possible to a room where no gas is burned. In cold frosty weather move it from the window at night.—E. H.

3977.—**Newly Planted Roses.** — If deficient in root and fibre, your Roses could hardly be expected to show much growth or bloom the first season after planting; and if by being "well fed" you refer to repeated applications of liquid manure, matters would be made worse, as this should be given to none but well established plants. In planting Roses from the nursery, first reduce any long naked roots, and cut back those that are bruised to the first fibres above the injured part. Have ready a compost consisting of two parts turfy loam, and one part each of well decomposed manure and sharp drift sand well mixed, and place a spadeful around the roots of each plant. Fill in and tread down firmly. This treatment induces the formation of fibres, and applies both to standard and self-rooted Roses. As regards the pruning, you are quite right. Whether the plant be a moderate or vigorous grower, if deficient in fibrous roots the head should be correspondingly reduced, and thus (to use a homely phrase) "fit the burden to the back.'—J. MARTIN.

3968.—**Pruning Banksian Roses.**—Banksian Roses flower on the late summer shoots; never on strongly grown ones. They should be pruned once a year in July, and not touched in the spring.

3966.—**Lime, Soot, and Salt for the Kitchen Garden.**—Lime and soot may be used in this case with great advantage. About one bushel of each will be a good dressing per rod. Less, of course, will have a correspondingly good effect.—H

3970.—**Summer Snowflake** (Leucojum æstivum).—Sow the seeds in spring in a pan or pans, and place in gentle heat till they germinate. Afterwards cool down and harden off. The second season, or when they require more space, prepare a nursery bed in the open air, and plant them out thickly to get strong. Afterwards they may be planted wherever required.—E.

3974.—**Best Rhododendrons.**—Two years ago I planted a circular bed with the following, supposed to be some of the best sorts: *Centre*—Lady Dorothy Neville. *First Circle*—Concessum, Leopardi, limbatum, The Queen. *Outer Circle*—Warrior, Prince Albert, Stella, Sir Isaac Newton, Purity, cruenta, Bylsianum, John Waterer, and Nero. They are planted in about 2 ft. of peat.—G. H. A.

3878.—**Camellias from Cuttings.**—I have succeeded by taking eyes and striking as one would Grape Vines. Place in well-drained pans, with peat and silver sand in a moderately warm house, with a bell-glass over. I often plant an eye when I cut a blossom.—G. H. A.

3983.—**Show Chrysanthemums.**—I think "W. J." will be satisfied with the following show Chrysanthemums: Empress of India, Mrs. George Rundle, White Venus, Mrs. Dixon, aurea multiflora, Geo. Glenny, Progne, Gloria Mundi, Mrs. Heale, Dr. Sharpe; and in the Japanese varieties Elaine and The Sultan.

4008.—**Soot Water for Plants.**—Will the settling or dregs of a rain-water tub serve as soot water for Rose trees or other plants? and will it do any harm given black as it comes from the tub, which has not been cleaned out for some time, with a little warm soft water added? What is the object of clearing soot water?—DIDO. [It may be given to Roses or other plants as it is, but the sediment on the surface of the soil must be stirred up occasionally, or it will cake and keep the air out of the soil.]

4009.—**Temperature for Camellias.**—Is a temperature of 50° hurtful to Camellias at this time of year? and what kind of manure water is best for them now that they are in bud? Also, will it harm them to shift them from a dirty pot to a clean one the same size?—DIDO. [The temperature is plenty high enough; do not exceed it. Also syringe the plants occasionally in the mornings when air is given. We would not repot them till they have done blooming, or they may cast their buds. Clear soot water, or a slight top-dressing of Standen's manure will be beneficial and safe.]

4010.—**Planting Out Ferns.**—I have a lot of Ferns in my greenhouse in pots, but as my spare time is limited I cannot always water them when they require it, and they get dry sometimes. I am thinking of planting them in a 2-ft. border in my greenhouse, but as the hot-water pipes run round the house I fear it would be too warm for them. I have also thought of plunging them in ashes, so that I could lift any of them for the house when required. Do you think the position would be too warm? they would be about a foot from the pipes.—DIDO. [If you put some slates or tiles against the pipes to keep the heat from the plants they will do very well, provided they are kept well supplied with water.]

4011.—**Geraniums for Winter Blooming.**—How can I manage Geraniums for full winter blooming, such as Vesuvius, Lord Derby, Wonderful, Madame Baltet, &c., and any other equally floriferous kinds? I want large plants covered with flowers.—ENFIELD. [If in spring you have some well-established plants, pot them on as required till they have reached the sized pot you wish them to flower in. Keep them in a warm, airy greenhouse, well exposed to light and sun, and keep all flower-buds pinched off; also stop the points of the shoots occasionally, to keep the plants dwarf. In June, place them in the open air in a sunny position, and give them just enough water to keep them growing. In September remove them to a greenhouse, where they can get plenty of air and a dry temperature of 50° to 60°. After this time all pinching and picking off flower-buds should cease. The soil should consist of good fibrous loam and sand. When in flower a little weak guano water may be given with advantage.]

4012.—**Violets.**—*Beech Park.*—A top-dressing of decayed manure will benefit them.

4013.—**Pelargoniums Blighted.**—*G. J. H.*—Keep them dry through the winter, and in spring cut them back close to the pot, and they will probably make healthy shoots.

4014.—**Transplanting the Glory Pea.**—*J. R. M.*—April or May will be the best time.

4015.—**Maiden-hair Ferns Eaten.**—*G. H. M.*—Search carefully by candle-light; there are slugs or snails somewhere about the plants.

4016.—**Pruning Currants and Gooseberries.**—*J. H. M.*—These may be pruned at any time during the next two months.

4017.—**Pruning Gooseberry and Currant Trees.**—I planted in November last Gooseberries (Crown Bobs) four years old. They have five, six, and seven upright branches, plenty of buds, and no shoots on them. Should these be pruned back? if so, when and how far? How many buds should I leave on each upright branch? The branches are about 2 ft. long. Also Currants (White Grape), with four or five branches, 12 in. to 14 in. long. When should I prune them back, and to how many buds? —NOVICE No. 1. [We would prune them back to about half their length, in order to get them furnished at the bottom.]

4018.—**Algerian Daisy.**—*Beech Park.*—Plant it out-of-doors or put it in a cold frame. The room is not airy enough for it.

4019.—**Sparmannia africana.**—Can you tell me how to propagate Sparmannia africana? I have a large plant about 5 feet high, and should like to have some smaller ones.—H. E. H. [Put in cuttings of the young shoots in sandy soil, in a warm house or frame, in March or April.]

4020.—**Abutilons.**—How should the Abutilon be treated? Mine has grown about three feet high, but has only leaves at the tips of the branches. It is in a 5-in. pot. How is it propagated?—H. E. H. [Cut it back in spring, and put in the tops of the shoots as cuttings, in heat.]

4021.—**Character of Chrysanthemums.**—*A. R.*—We cannot find room to describe Chrysanthemums. Get a descriptive catalogue from some good nurseryman.

4022.—**Edelweiss.**—*Thos. E. M.*—Pot it in sandy soil, to which may be added a handful of potsherds broken to the size of horse beans. Keep it in a cool, place, and water when necessary.

4023.—**Nicotiana longiflora.**—I purchased two small plants of this from Gibbs & Co., but the foliage as fast as it is produced withers off from the top of the leaf. Will any one kindly tell me the soil that suits them, and how they are to be treated as regards heat? I would say that I have a greenhouse heated with a brick flue and the temperature is about 46° to 48° in frosty weather.—AN OLD SALT.

4024.—**Sowing Tulip Seed.**—I have purchased some Tulip seed. What would be the best time for sowing it? also the kind of soil it would grow best in?—CONSTANT READER.

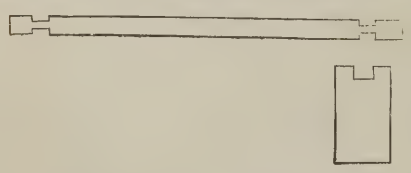
4025.—**Plants for Shady Border.**—I have a garden border which is totally shaded from the sun, and is also rather damp. Will any reader kindly give me the names of some plants that will grow in such a border?—FLEUR.

4026.—**Preserving the Pampas Grass.**—Can any one tell me how to preserve the plumes of the Pampas Grass in their natural state? I have often tried, but have always failed.—J. C.

BEES.

EXPERIENCE IN BEE KEEPING.

Bar-frame Hives.—In making bar-frame hives the first consideration is the size of frame to adopt, then make a pattern of it for future guidance, as it is of great importance that all hives, frames, &c., should be of the same dimensions, so as to be interchangeable. The "Standard" frame, 17 in. by 10½ in., is a great favourite with many, but I find it too large for this locality. With a large frame you sometimes have a difficulty in abstracting honey without disturbing the brood nest, and with them you cannot very well make a small hive; whilst on the other hand, with smaller frames, you can build up hives to any size you like. For these reasons I fixed upon the Woodbury size, which is in general use, as the one best



adapted for my purposes. The first frames I made were exactly similar to those recommended to cottagers by the British Bee-keepers Association in their "Handbook of Modern Bee-keeping," published last year; but finding, as I have stated before, a great waste of heat round the end of the frames, I discarded them, and now use a frame made of three pieces of wood, the top bar of ½-in. wood, 7-8 in. wide and 15½ in. long; at ⅞ in. from each end a slot is cut out on each side ¼ in. square, and a groove cut 1-16 in. deep along the centre of the underside for fixing in guide comb; the two other pieces are of 3-8 in. wood, 1½ in. wide and 9 in. deep; at one end of each a slot is cut out of the centre ½ in. square, then you will find the top bar fits into firmly. No nails are required, and they will thus be found handy for taking to pieces for cleaning or storing; if preferred nailed, French nails or shoemakers' rivets are the best to use, one at each end sufficient. I do not use a bottom piece to the frame; it is only useful in transferring comb, &c., which will soon become a thing of the past when the wooden comb foundation is brought within the reach of all. If a bottom bar is preferred it should be of ¼-in. wood, ½ in. or ⅝ in. wide, nailed inside the end pieces at ¼ in. from the bottom. These should all be cut out by a circular saw to obtain uniformity of size, but if this is not obtainable and time not very precious, they can easily be cut by hand, but as I can purchase them at 1s. 6d. per dozen I prefer doing so. Now there are so many different ways of making the hives to fit the above frames, the simplest one I have used, in which a late swarm has done well, consisted of nine frames placed side by side, a board back and front, with an entrance hole cut in the latter, a piece of strong calico over the top, he whole pasted over with brown paper; of course for wintering I remove the paper from the top and substitute some warm porous material; old bags will do. This hive will require an outside cover. I have made a combination hive, such as is sold for £2 or £3, out of an American bacon box costing 1s. with the aid of a few feet of ½-in. boards, that would hold two stocks with twenty frames in each. This is done by simply nailing two 8½-in. boards along the middle for the ends of frames to rest on; a 2-in. plinth nailed along the top of them to cover the ends of the top bars; the frames will give the distance the boards should be apart; the ends of frames fitting easy inside the plinth, and the bottom of end pieces of frames resting on bottom of box; an entrance is made at each end 5 in. by ¼ in. full, with an alighting board (perforated zinc makes a good one). A division is placed in the middle the same height as the plinths, so as to make two hives; these are fitted with frames and a dummy board, and when filled with comb, thirty-two super boxes are piled above each; or if a slinger is used another height of frames is added. The only objections to this plan is you cannot well disturb one stock without the other, and it is much more convenient to have each hive separate and easily removable. Intending bee keepers should send 6d. to Abbott Brothers, Fairlawn, Southall, for one of their catalogues and the Crystal Palace leaflets, which give the best information on all matters of bee keeping. —BAR FRAME.

POULTRY.

BRAHMA FOWLS.

VERY little is known of the history of the Brahma fowl. In 1857 Martin Doyle, writing of them, says, "They are yet too scarce to have entered into our private possession, and as to tasting their flesh—an experiment which we long to make—such an extravagance has not yet been committed in this country." Now they take precedence of all other fowls at shows, they are running in almost every poultry yard, and they are to be seen in every poulterer's shop.

Mr. Wright, who has taken great pains to ascertain among much conflicting discussion the true story of their introduction into America, from whence they came to this country, says that in 1840 some Indian sailors brought from Luckipoor, a port on the Brahmapootra river, three of these birds to New York. They were purchased by a Mr. Chamberlain, of Connecticut, and chickens descended from these birds were first exhibited in 1850. Mr. Wright maintains that they are a distinct species, and not, as some suppose, an improved variety of the Cochin. He points out the important fact that while the crop of the Cochin is above the normal position, that of the Brahma is below it. Another point of difference is, that the Brahma chickens closely resemble their parents in plumage, while it is extremely difficult to breed Cochins true to colour.

There are two varieties, the light and the dark Brahma, but their carriage, shape, and style are precisely similar, the difference alone being in the colour of the plumage. The hen should be very small and short, but broad over the eyes, causing the sort of frowning brow so often seen in well-bred Brahma pullets. It is not so noticeable in the cock, but is to be seen if looked for.

The comb should be what is called a pea-comb. It is divided into three ridges, the middle ridge being slightly higher than the two outside ones, the whole not exceeding ½ in. in height. Single combs were originally common in this breed, but the pea-comb is now necessary for exhibition.

The beak should be very short, strong at the base, and slightly curved.

The tail short and upright, the two highest feathers coming outwards away from one another. The wings should be small, and the points well tucked under the tail hackles. Cockerels that get driven about the run by older birds often contract a habit of turning the outside feathers of the wing the wrong way. This should be attended to, and some mechanical contrivance used to keep them flat. The back should be wide, and very flat.

The legs a rich orange colour, covered down to the points of the third and fourth toes with soft curling feathers. Straight stiff feathers on the joint constitute what is called a "vulture hock," and is a great defect. The birds should carry themselves in a very proud and stately fashion, according well with their great size and weight.

In light Brahmas both cock and hen should have a pure white head; the hackles of the neck white, striped very clearly with black down the centre. The breast, underpart, and downy feathers white; the wings appearing white when closed; but the inner web, only seen when the wing is open, should be black; the tail rich glossy black with green reflections.

In the dark Brahmas the head should also be white, and the hackle feathers white with the black stripe, but the back and breast, the tail coverts, and tail should be black, also the leg feathers; these latter may be black and white. The top edge of the wing should be black, the lower part white.

The hens of dark Brahmas should be a steely grey, showing white only on the hackle feathers. The light Brahmas are the more ornamental, but it should be borne in mind that a light-coloured fowl is usually more delicate than a dark one.

Brahma chicks are extremely ugly up to about four months. They are long in feathering, and their long legs seem out of proportion, but the worst-looking chicks often turn out the best birds. They require a great deal of Grass; it should be cut up small, and mixed with their soft food to ensure their eating sufficient, if they have not a Grass run.

In setting Brahma eggs great care should be taken in preparing the nest. It needs to be made much damper than that for other fowls. It is a good plan to put a deep layer of cut Grass at the bottom, then some Cocoa-nut fibre, and on the top dry Fern leaves. Insects dislike Bracken Fern, and it makes in all cases very good nests. If the weather is very dry just as the chickens are due, pour about a pint of warm water round the nests on the nineteenth day. Many Brahma chicks are lost, because the shells being so thick, the sticky substance inside gets hardened to the consistence of glue before the little creature can get out. Only moisture will prevent this. M. A.

Brahma Fowls.—I have a dark Brahma cock that has several black feathers in his tail that are mixed with white. I should be glad to know whether or not such a bird would produce good chickens, and if so, would he be best for breeding pullets or cockerels?—NOVICE.

THE HOUSEHOLD.

How to Cook Haricot Beans.—Some weeks since a correspondent asked if any reader could give the French way of cooking these Beans. I have been waiting for this answer, and now repeat it, as I am very fond of this highly nutritious vegetable, and should be glad of any improvement on the following simple way of cooking them. We soak them over night in cold water; in the morning we wash them, and put them on the fire in cold water with a large lump of salt. When they boil up, we draw the saucepan off the fire, and let them simmer gently for about 2 hours or a little more, until they commence to crack, strain them off, and work in a piece of butter about the size of a Walnut or larger, and some fresh Parsley chopped very fine. Those who like the flavour may add a sprig or two of Mint whilst boiling.—FERNDALE.

SECOND VOLUME OF GARDENING.—Our second volume will be completed at the end of February, and an index and frontispiece will be issued shortly afterwards.

GARDENING ILLUSTRATED.

VOL. II.—No. 97. *SATURDAY, JANUARY* 15, 1881. PRICE ONE PENNY. REGISTERED FOR TRANSMISSION ABROAD.

INDOOR PLANT CASES.

THERE are few domestic occupations for the leisure hour more deserving of encouragement than the cultivation of plants in the dwelling house. The Wardian Case has long since become a common article of furniture, and it may safely be asserted that as much real pleasure and instruction are often afforded by these miniature greenhouses as by vastly more ambitious structures. The number of plants which may be satisfactorily grown in an ordinary closed case is far from small; but the enthusiast will certainly wish to add to his collection some of the very beautiful forms of vegetable life to be found among the tropical Ferns, Orchids, and so-called fine-foliaged plants. The gratification of this desire will render it necessary that some arrangement be provided for warming the little greenhouse and transforming it into a small stove or hothouse. Hitherto heated plant-cases have not been largely made and sold, though various forms have been from time to time devised; but there can be no question that their use will be much extended as the advantages they offer in the cultivation even of such plants as are now grown in the ordinary Wardian Case become more appreciated. At the present time the choice of ready-made plant-cases with heating apparatus is limited, and the critical in such matters will probably prefer to construct their own in order to consult their individual tastes on various points of detail. It is with a view of assisting those who have reached this conclusion that the following description has been written. The arrangement set forth has been practically tested by the writer with most satisfactory results, and a strict adherence to the dimensions given may, on this ground, be recommended, but it will be obvious that in these and many other particulars deviations may be made to suit individual circumstances without necessarily impairing in any way the efficiency of the whole. Fig. 2 (A) represents a rectangular box, 3 ft. 5 in. in length, 2 ft. in breadth, and 2 ft. 5 in. in depth—all external dimensions. This box, which should be of 1-in. well-seasoned deal, strongly dove-tailed together, is provided with a false bottom (*b*) securely fixed, so that its upper surface is 9½ in. from the top of the box. In what may be termed the front of the box two doorways are cut, as shown in the figure, each 15½ in. high and 12½ in. wide. The doors for these openings are provided with two projecting studs fitting into corresponding depressions where hinges would ordinarily be placed; the reason for which arrangement will presently be obvious. Between the true and false bottoms of the box two partitions

HEATED PLANT CASE. (Open).

(*c c*) are fixed, as shown by the dotted lines, at 12 in. and 13½ in. respectively from the front and left-hand (as the reader looks at the figure) end of the box, thus forming a chamber of these dimensions as to depth and breadth, and of 17 in. in height. This chamber is for the reception of the heating apparatus, and it is essential that air-communication between it and the rest of the box be entirely prevented by caulking all the joints and angles with a mixture of red and white lead with linseed oil, and by screwing over them slips of wood with the interposition of felt smeared with the same compound. Two holes (*d d*), 2½ in. in diameter, are bored through the left hand end of the box at the top and bottom of the apparatus chamber, so as to provide for the ingress and egress of air to and from the source of heat. At the opposite end of the box a circular orifice 9 in. in diameter is cut, equidistant from the sides and bottoms, and is provided with a circular zinc ventilator of the ordinary form, having a button in the centre, by means of which the openings in the outer plate may be wholly or partially covered by the under plate. A number of 1½-in. holes are bored through the false bottom, say 2 in. apart, omitting that portion which forms the roof of the heating apparatus chamber. At a distance of ½ in. from the front, back, and sides of the box, a continuous strip of wood, ½ in. in thickness, is screwed to the upper surface of the false bottom, with the interposition of stout flannel or felt smeared with the red and white lead mixture, so as to form a water-tight channel or gutter (*f*); and in this channel two holes are bored through the false bottom, into which pieces of ⅜-in. composition tubing (*g g*) are fitted, so as to convey any water from the channel into a pan to be placed in that portion of the box communicated with by the right-hand door. These holes may be at the back and front of the box and midway between the ends, and the composition pipes may be bent as shown by the dotted lines, so as both to deliver into the same pan. Fig. 2 (*h*) represents the receptacle for the soil, consisting of a trough or tray 3 ft. 1 in. in length by 1 ft. 8 in. in width (both outside measurements at the top), and 9 in. in depth (outside), the sides tapering somewhat towards the bottom. This trough should be strongly made of ¾-in. deal, lined with thin sheet lead or stout zinc, and the bottom should be perforated to receive a piece of 1-in. lead pipe (*i*), which passes through the false bottom of the box when the trough is placed in its position, and delivers into the pan already mentioned. Over the inlet of this pipe an inverted saucer of perforated zinc is placed to act as a drainer. Across the bottom of

the trough outside, several strips of wood, ½ in. in thickness, are nailed, so as to form a bearing and to admit of air freely passing under the trough from the orifices in the false bottom of the box. The trough is not shown *in situ*, in order to simplify the figure; but it will be obvious from a consideration of its dimensions that when resting upon the false bottom of the box there will be a space surrounding it 1 in. wide at the top (the space increasing towards the bottom in consequence of the tapering of the sides) through which the heated air from the hot-water pipes, presently to be described, can

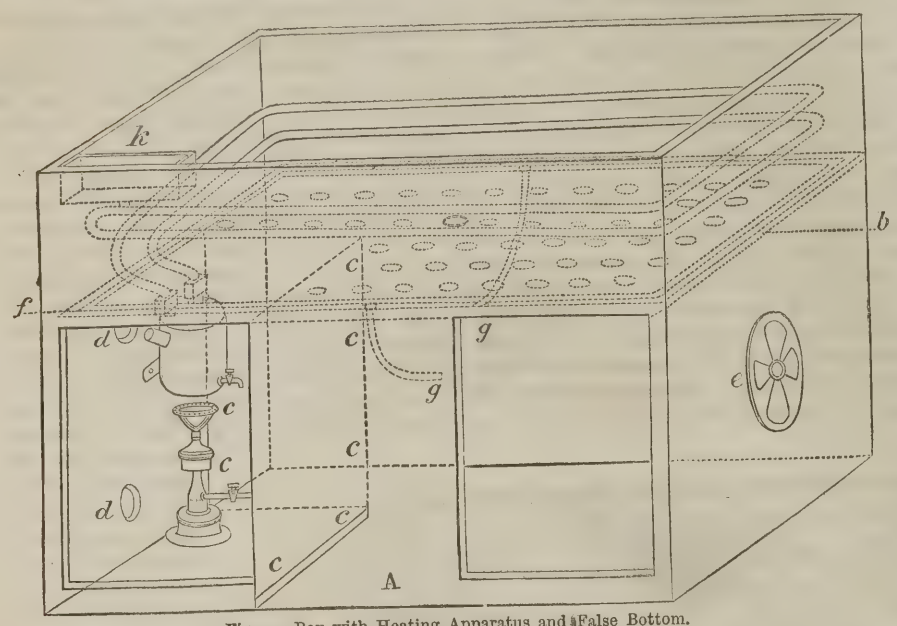


Fig .—Box with Heating Apparatus and False Bottom.

freely ascend. This air-space being in communication, through the perforations in the false bottom, with the larger chamber on the right-hand side of the box, it follows that the ventilator already mentioned affords a means of regulating the air current passing over the pipes. For the sake of appearance a strip of perforated zinc with large apertures may be fixed over the space between the trough and the sides of the box.

The Heating Apparatus should now receive attention. Fig. 3 represents the boiler, which is of stout sheet copper, 4½ in. in diameter by 5 in. in height, and provided with a flue (*a a*) tapering from about 2 in. in diameter at the lower end to about 1 in. at the upper. The boiler is fitted with two unions (*b c*) at the top, one of which (*c*) carries a piece of 1-in. pipe (*d*) passing nearly to the bottom, and a small tap (*e*) is placed at the lowest point to draw off the water when required. A copper strap (*f f*), soldered to the boiler, serves to fix it to the side, or preferably in the angle of the apparatus chamber, and it should be placed as close to the roof as is convenient, in order to leave as much room as possible beneath for the lamp. The boiler may advantageously be provided with a well-fitting felt jacket to check the radiation of heat from its surface. In fixing the boiler, the orifice of the flue should be turned towards the upper hole in the end of the box, so that an elbow may be fitted on, if desired, to convey away the products of combustion. From the union (*b*) a piece of 1-in. lead pipe passes through the false bottom, along the left-hand end and so round the case, as shown in fig. 2, until it reaches the left-hand side of the front, gradually rising as it goes until it is 3 in. or 4 in. from the top. Here it is doubly bent and it passes back beneath the first coil, finally re-entering the apparatus chamber, and being connected with the union (*c*). Thus is provided a flow and return pipe, altogether about 19 ft. in length, and having between 4 and 5 square feet of heating surface. The openings through which the coil passes through the false bottom must be carefully caulked to make them air-tight, and in attaching the coil to the sides of the box thin strips of wood should be interposed to keep the pipes from contact with the sides. Into the highest point of the coil one end of a short piece of ¼-in. composition tube is soldered, the other end being similarly attached to the bottom of the small water-tank (*k*), which is fixed to the side of the box, so that the tops are flush. This tank may be 8 in. long by 1 in. wide, and 2½ in. in depth. As a

Source of Heat the writer would recommend gas, where it is laid on, and in many cases the supply pipe may be conveniently brought through the floor of the room, and directly through the bottom of the case to the burner. In the selection of the burner something will depend upon the locality as influencing the general temperature of the apartment, and upon the extent to which the room is used. In a cold room, that is to say a room where there is seldom a fire, and in a cold locality it will be best to have a ring burner, 2 in. in diameter, pierced with a dozen holes. This, placed at a distance of 1 in. from the bottom of the boiler, will give abundance of heat in the coldest weather. Of course where little heat is wanted the ring burner may still be used, and the gas supply checked to the necessary extent, but in such cases it will be found that an ordinary steatite fish-tail or bat's-wing burner turned down low is more convenient. And here we come to the consideration of a most important question. Shall we make the regulation of the gas, and consequently of the heat of the case, automatic, or not? Some there are who are ready to affirm that it is quite useless to attempt the heating of so small a structure unless an automatic regulator be provided, and they confidently predict the freezing or frying of the contents as a necessary consequence. The experience of the writer is, however, entirely opposed to this view. With the heating apparatus already described he has found no difficulty in regulating the temperature without the use of any automatic apparatus, even when the case has been left for days unattended to. Of course violent fluctuations in the temperature out-of-doors will produce alterations within the plant-case, but not nearly to the same extent as if the case were in the open air; and if any thing like daily attention can be given, even for a couple of minutes, these fluctuations can be easily counteracted after a little experience. Besides which it is not as if the temperature were the only point requiring attention; the ventilation of the case is an equally important matter, and inasmuch as the rate of passage of the heated air through the openings provided depends upon the difference of the temperatures of the air inside and outside the case, it follows that whenever the heat is increased under the boiler the ventilator openings should be decreased, unless one desires to expedite the ventilation, as for instance in damp weather or in winter, when the case is required to be kept freer from moisture. The only kind of regulator which the writer would recommend is Sugg's Governer, which is useful in keeping the pressure of gas uniform. This little apparatus is now commonly attached to the street lamps, and may be procured for a few shillings. The pattern selected should be that which admits adjustment for any desired rate of consumption of gas, however small. The Governor screws on to the cast-iron pedestal of the lamp beneath the burner.

In case, however, the reader should prefer to have an automatic heat-regulator, the following description of a suitable arrangement is given: Fig. 4 *(a)* is a water-tight box of thin sheet zinc, 6 in. long by 4 in. deep and 1 in. wide. Into the top of this box is soldered a brass tube (*b*), about ¼ in. in internal diameter, bent at right angles at about 6 in. or 7 in. from the box, and terminating at *(c)*, where it is connected by a piece of india-rubber tubing with a glass tube (*c c*) of the same diameter and bent as shown in the figure. Over the tube (*c c*) is fitted by means of a cork a larger tube *(d)*, about 1 in. in diameter, and 5 in. or 6 in. in length, and through the same cork is passed a tube (*e*) bent once at a right angle. The upper end of the large tube is also closed by a cork which carries a glass tube *(f)*, bent once at a right angle, and sufficiently small to pass loosely into the tube *(c c)*. The metal box and tube are filled with water (boiled to expel the air), and the upper part of the tube (*c c*) is similarly filled. The lower part of the tube (*c c*) is filled with mercury, care being taken that there is no air between the mercury and the water, and no water above the mercury in that limb of (*c c*) into which the tube (*f*) passes. The apparatus is placed in the plant case at the temperature which it is desired to maintain, and left there until the water ceases to expand under the influence of the heat, and drive the mercury forward. The tube (*f*) is then adjusted, so that its orifice is only just closed by the mercury. The apparatus may stand upon the hot-water pipes at the end of the case, where it will be less unsightly than elsewhere, but under these circumstances it will maintain a uniform heat in the pipes rather than in the atmosphere of the case. For use with this regulator the gas burner will require to have two small tubes soldered into the supply pipe, one on each side of a small tap, as shown in fig. 4. These tubes are to be connected with the tubes (*e*) and (*f*) of the regulator, and for this purpose it will be convenient to fix, air-tight in the roof of the apparatus chamber, two small tubes close to the end of the case, the connections with these being made of india-rubber tubing. The action of the apparatus will now be seen. The tap of the gas burner between the two small tubes should be turned on only so much as to give a supply insufficient to provide enough heat, and indeed

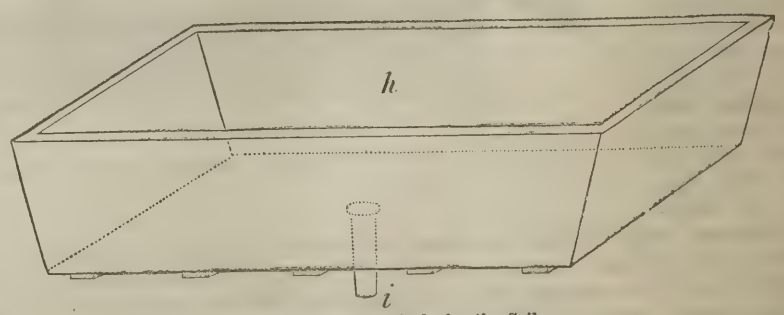

Fig. 2 *(h)*.—Receptacle for the Soil.

the only use of this "by-pass" is to prevent the extinguishing of the gas by the action of the regulator. As the temperature of the air in the case falls the water in the metal box contracts, the mercury recedes, the orifice of the tube (*f*) is uncovered, and gas passes through it, up the annular space between (*f*) and (*c c*) into the large tube (*d*), through the tube (*e*), and so to the burner, which it continues to supply until the increased size of the flame has so much raised the

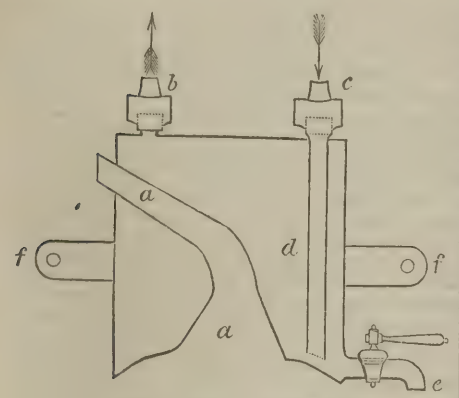

Fig. 3.—Section of Boiler.

temperature of the case that the expansion of the water in the box has again, through the medium of the mercury, closed the orifice of the tube (*f*), and stopped its passage. Where gas cannot be used for heating, the best substitute is a mineral oil lamp, with a flat wick ⅝ in. in width, provided with a chimney of metal and talc, and having a shallow oil reservoir of large diameter. The lamp should be fed with "water-white petroleum oil." The

Decoration of the Case should now be proceeded with, in order that the inelegant deal box depicted in fig. 2 may be converted into the handsome pedestal represented in fig. 1. Three mouldings should be provided. The upper one may be about 1 in. in width, and should be put on so that its edge is about ⅛ in. above the top of the box, and it will be well for the top of the box itself to be slightly bevelled, so that its inner edge is somewhat the lower. This will prevent any accumulation of the water, which may be condensed on the glass. The middle moulding may be about 2 in. in width, and it should be about 2 in. in thickness at its lower edge, which should be 7 in. from the top of the box. The lower moulding at the bottom of the box should be somewhat bolder than the middle one. The surface of the box, including the doors, comprised between the middle and the lower moulding, should be covered with virgin cork, broken into small pieces for convenience of fitting, and fastened on with French nails.

Upon the care which is expended in this operation the appearance of the case when finished will largely depend, and whatever else is entrusted to the workman, the writer would recommend this being done by the amateur. It is more a question of patience than of skill, though a prolonged study of the Chinese puzzles of our infancy would be a fit preparation for the task. A ½-cwt. bale of the cork will be more than enough, and will permit of the rejection of the less suitable pieces. It will now be seen why the doors of the pedestal are not hung on hinges, for of course if they were, being covered with cork, they would not open unless an unsightly blank were left. By the method of fitting recommended, the joint may be made so neatly that the doors are almost invisible, and they require no fastening to keep them shut. The cork surface should be sized and well varnished, and the woodwork may be painted a dark olive-green and bronzed or ebonised, and the mouldings gilt.

The quondam plain deal box will now present the appearance of a receptacle for the soil, resting on a handsome solid pedestal, and is ready to receive the glass superstructure. This part should be made by a specialist accustomed to the work, and there is some room for difference of opinion as to its form. The arrangement shown in fig. 1 is convenient, the two doors in front affording easy access to the contents; but a simple sheet of glass for the front and back, with the ends to open as doors, may be considered by some to have a better appearance. Whether the doors are at the ends or in front, they must fit well. The curved top, though more costly, is worth the extra price. On the summit is the ventilator, consisting of two strips of glass sliding in a groove 1 in. in width, and slightly overlapping in the centre when the ventilator is closed. By sliding them over each other to a greater or less extent, corresponding openings for the escape of the heated air are left at the ends of the groove. The glass case should have a strong wire passing from end to end beneath the ventilator for the support of hanging baskets, and another wire should be stretched across each end on a level with the tops of the doors. The following dimensions will be found suitable, and a structure of this size, made of stout glass and strong zinc angle bar (which should be painted to match the pedestal), will not be too heavy to be easily lifted on and off by two persons: Length, 3 ft. 4 in.; breadth, 1 ft. 11 in.; height to top of doors, 2 ft.; total height, 2 ft. 11 in.

Situation for the Case.—The selection of a suitable position for the case will probably have been made before its construction was commenced. As to aspect, much will depend upon the character of the plants to be cultivated. Plants with brilliantly coloured foliage and most flowers cannot, it is well known, be grown to advantage without strong light; and, on the other hand, Ferns will not thrive if exposed to sunshine. A sunny spot may of course be shaded, but this precaution may on some occasion be neglected, to the injury of the occupants of the case, and it will, therefore, probably be the wisest course to choose a northern aspect where possible. It has been already mentioned that the orifice of the flue of the boiler should be turned to the opening in the end of the box, so that an elbow

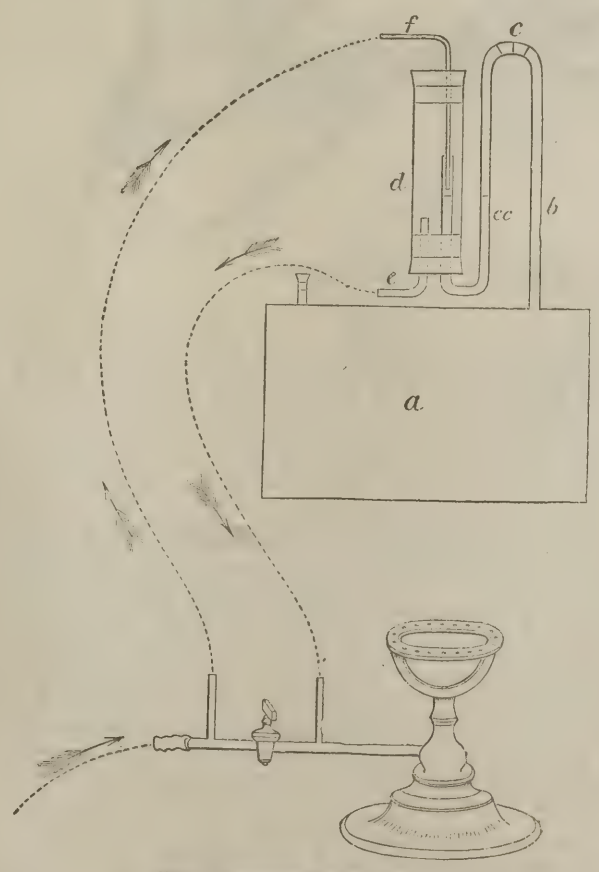

Fig. 4.—Automatic Heat-regulator.

may be applied to carry off the products of combustion. This is not a necessity, but where convenient it would certainly be well to adopt it, and the elbow should preferably pass through the wall or window-frame, and terminate in the open air.

The construction of the plant-case having been completed, and the little boiler with its circulating pipes filled with water, heat may be applied, and the bed of soil prepared for the reception of the plants. Covering the bottom of the trough should be a layer of potsherds at least 2 in. deep, the largest fragments at the bottom, and with these may be advantageously mixed some pieces of charcoal; over this layer should be placed a stratum of dried Moss to prevent the earth from passing into and choking the drainage; and lastly the trough should be filled to within 1 in. of the top with the compost, which may consist of good fibrous peat mixed with plenty of silver sand, to which may be added loam when planting those subjects which require it. The surface of the soil may be diversified by the formation of slight hills and dales, and by placing here and there, half-embedded, a few fragments of porous stone. The earth should then be thoroughly saturated with boiling water, which will destroy any animal or vegetable life present in it, and next day the case will be ready for the plants.

Stocking the Case.—On the subject of stocking the case, the writer proposes to suggest little beyond giving the names of various plants which he has practically found to succeed well. In planting a case, as in laying out a garden, written descriptions are of little use, and almost everything must be left to the taste of the operator. Nevertheless, a few general hints may be of service. It is well to line, as it were, the ends and back of the case with tall-growing Ferns, so as to form a good dense background of verdure; but uniformity of height in the plants thus arranged must be avoided, so as not to produce anything approaching to a straight line. In the rest of the case marked contrasts as to height and form should be aimed at, and a few distinct plants springing from a carpet of dwarf plants will be more effective than a number nearer alike in character. Above all things, a crowd of plants should be avoided, and room should be given to each to develop and display its beauties of form, all large-growing plants being thus necessarily excluded from a case of the dimensions given, unless one is prepared to keep them only so long as they remain in a small state. Again, no supporting or training of the plants is admissible, for it is essential that they should appear to be growing quite naturally. Passing from generalities, the following arrangement is given as one which will be found to afford satisfaction: As a background Pteris serrulata cristata, P. s. angustata, and Adiantum affine. In the centre of the case a well-grown Palm—say Areca lutescens. At the ends of the case, A. assimile, A. cuneatum, A. concinnum latum, A. Sanctæ Catherinæ, and Cheilanthes elegans. Difficulty is sometimes experienced in the management of some of the large-fronded Adiantums, especially in the winter, but the writer has found A. Sanctæ Catherinæ to thrive well in the heated case. The very beautiful A. macrophyllum cannot, unfortunately, be recommended for the purpose, though it may be preserved in good condition through the summer. Towards the front of the case may be planted the graceful Asplenium viviparum; right and left of the Palm, Maranta rosea picta, M. Makoyana, M. chimboracensis, and a small plant of Alocasia metallica, the splendid foliage of the Marantas and Alocasias contrasting well with the Ferns. A. metallica will soon grow too large, but not before it has well paid for the

rouble of its removal. Space should be preserved for a plant of Anthurium Scherzerianum, which will thrive and produce its brilliant spathes with a little care. A specimen may also be added of the New Holland Pitcher-plant (Cephalotus follicularis), and of the interesting little Venus' Fly-trap (Dionæa muscipula), though the writer has found it impossible to preserve the latter in an active condition—probably in consequence of its receiving insufficient light. If possible, room should be found for at least one species of Cypripedium, say C. insigne, C. barbatum, or C. niveum. The pretty little Fittonia argyroneura, F. Pearcei, and F. Verschaffelti are also useful for filling nooks. All vacant spaces should be carpeted with the common Selaginella, the beautiful blue S. cæsia, and the compact S. apoda, and a small plant or two of Tradescantia zebrina and Cyrtodeira fulgida may be added.

From the top and sides of the case should be hung a few Orchids in baskets, which will succeed well without more care and attention than they require in the Orchid house. It will be found in all cases that the cooler-growing Oncids do remarkably well, and, in fact, the writer has had blossoms of Oncidium flexuosum as good as could be wished for produced in the plant case. A further selection may be made from the various species of Lycaste and Odontoglossum, and those who admire its blossoms may add a plant of Sophronitis grandiflora, which is best grown on a small block. In addition to the Orchids (which may be advantageously planted

The Spire Lily Hyacinthus candicans).

in home-made baskets of virgin cork), plants of Æschynanthus fulgens, Panicum variegatum, and Tradescantia zebrina may be suspended from the upper part of the case. Isolepis gracilis cannot be recommended for this purpose, as it is difficult to keep it sufficiently well watered. The arrangement thus sketched out may of course be modified in all cases by the substitution of many other Ferns for those named, as, for instance, Phlebodium aureum (selecting a small specimen), Pteris cretica albolineata, Gymnogramma chrysophylla, &c., and by replacing the Marantas by Caladiums or by variegated-foliaged Begonias; but although such Caladiums as C. Chantini and C. argyrites brighten up the case wonderfully, they possess the great objection that their places are necessarily blank during the winter; and, in fact, no deciduous plants can be altogether recommended as suitable for the case. Again, the Areca lutescens may be replaced by a Dracæna or by a different species of Palm, and by none better than Cocos Weddelliana, if expense be no consideration.

Those who have had no experience in the indoor cultivation of plants may be glad of a few suggestions as to the management of the case. The temperature at which it is kept may, for such a collection as that described, be, during the summer, about 70° Fahr. in the day, and somewhat less at night—the gas remaining at the same height, the decrease in temperature of the room will do all that is needed in diminishing the heat. It may be objected that the most fitting temperature for the cultivation of the Marantas, Caladiums, and other fine-foliaged plants enumerated is somewhat higher than that which would be recommended for some of the Ferns with which they are associated; this, however, is an evil inseparable from every mixed collection, whether in a house or case, and it will be found that the intermediate temperature specified will sufficiently meet the requirements of both classes of plants. During the early part of the summer, when the plants are making new growth, ventilation should be carefully attended to, so that the atmosphere may not become unduly dry; and it will be found advantageous to have two or three small water-tanks, made of sheet zinc, about 4 in. long by 1 in. wide, and of such depth that when resting on the hot-water pipes their tops are level with the top of the trough containing the soil. These tanks are to be filled with water, which by its evaporation will keep the atmosphere of the case charged with moisture. In addition to a dry-bulb thermometer hanging in the case to indicate the temperature it will be well to have a wet-bulb thermometer in the same frame, the two constituting a hygrometer, and in the summer there should not be at any time a difference of more than 2°, or at most 3°, between the readings of the two thermometers, while the nearer the indications are the better. While striving to maintain a sufficiently humid atmosphere, the operator must see that enough ventilation takes place at the same time, or the Orchids and some of the other plants will suffer. This is regulated, as already described, by the revolving ventilator at the end of the base or pedestal, and by the glass slides on the top of the case. There is, however, more danger with a heated case of having too much ventilation than too little, and in fact it will sometimes be found necessary to cover the glass slides with a strip of felt to further check the escape of air through the crevices. The condition of the glass will afford some criterion as to the state of the air; the surface should not be quite dry, but need not be allowed to become so much bedewed with moisture as to obscure the contents of the case. The watering of the plants (with the exception of those in baskets) will not require to be very frequently attended to, in consequence of the large bulk of the soil; once a week will usually be as often as it is required (though some of the plants will enjoy a more frequent dose if the drainage be good), except round the edge, where the contiguity of the pipes causes more rapid desiccation. Of course the supply of water to the little tank of the hot-water apparatus must not be neglected, and it will be well to have a slip of glass to act as a cover and check evaporation, when the tank will not require filling so frequently. In winter the temperature of the case may be allowed to fall to 50° or 60° Fahr., and the atmosphere, as well as the soil, should be kept drier by somewhat freer ventilation and less frequent watering.

Mildness of the Season.—I picked, on Jan. 5, from a small garden by the sea, the following flowers: Gloire de Dijon and monthly Roses, white and blue Violets, Primroses, Antirrhinums, Marigolds, Christmas Roses, Stocks, French Marguerites (off a large tree), Virginian Groundsel, winter Jasmine, Veronicas and a large handful of Mignonette.—*Sandgate, Kent.*

—— The following flowers were picked in the open air on Christmas Day in a garden in Dorsetshire: Violet, Primrose, Primula, Pansy, Polyanthus, Eccremocarpus, Mignonette, Marigold, Virginia Stock, Wallflower, Brompton Stock.—R. C. C.

THE AUTUMNAL SPIRE LILY.

(HYACINTHUS CANDICANS.)

THIS is one of the most interesting of all large-growing bulbous plants, and one which has proved to be hardy in many gardens. In waxiness and purity the flowers of this Hyacinth are indeed almost comparable with those of Lapageria alba, and that their effect is heightened by the black anthers, which form such a prominent feature in the blossoms. Even in cold or bleak localities the plant might be grown in a corner, sheltered by plant-houses, or beneath a sunny wall, for it is well known that many Cape bulbs, such as Crinums, Ixias, Watsonias, and even such plants as Hedychium Gardnerianum, Lilium giganteum, and tropical Solanums are perfectly amenable to open-air culture, if planted close to the foot of a warm plant-house wall. As a general rule, however, this Hyacinth is well able to take care of itself, if well planted in a deep, rich sandy border, sheltered from cutting eastern winds. It may also be successfully grown in pots for the autumn decoration of the greenhouse. In spring the pots should be plunged half their depth in coal ashes in a sunny position in the open air.

The bulbs of this plant may now be obtained in quantity. They are sometimes advertised at 10s. per dozen, but by the hundred they would be much cheaper, and for cut flowers the plant would be worth twice the money for its wealth of refined wax-like flowers.

Double Wallflowers.—I thank "Burns" (ans. 3830) for calling attention to the scarcity of the old double blood-red Wallflower, which has been much neglected of late years, and I may add the old English double yellow Wallflower, for border or pot culture, would well repay time and trouble bestowed upon it. Allow me also to ask if the old crimson Globe Dahlia cannot be brought prominently forward again? I was the means of keeping and supplying it in my neighbourhood for several years, but ultimately lost it myself. I consider it was the most perfect in form, colour, habit, and constant flowering of any of its class; in symmetry it was a perfect gem.—NORTH NORFOLK.

Clothing Stems of Standard Roses.—It is seldom we see any attempt to hide, or rather to decorate, the naked stem of the standard Rose. There are not many plants suitable for this purpose, and to which no objection can be urged. In my opinion nothing is so well adapted as the Petunia, of the cultivation of which you give so good an account in No. 93. Three or four plants of the single variety should be planted at the base of each tree, and the head will be found to afford some little shelter from rain, a considerable advantage to plants like this whose flowers are of somewhat flimsy texture. With the exception of tying up as they advance in height, they will give no further trouble, but remain in continuous bloom the whole summer, greatly adding to the beauty of the garden, more especially when the standard Roses are placed as usual round the lawn.—J. V. A.

Salvias for Winter Flowering.—These form such useful plants for furnishing conservatories where large masses of colour are required, that the most expeditious way of getting up a good stock of them is of importance when such structures are required to be kept gay at this season. I have tried the plan of planting out such varieties as splendens, Heeri, and gesneræflora, but although larger plants may be grown with less attention as to watering, &c., than by confining them in pots, I am convinced that more floriferous and altogether better plants may be grown by the latter method, as, being of a strong-rooting and gross-feeding habit, they become over luxuriant if planted out in good soil; and, as is well known, a short-jointed, well-ripened growth is conducive to free flowering, it follows that pot culture is mos likely to attain that end in the case of such subjects as the Salvia, and on the score of

economy of labour there is not so much real as apparent saving by the planting-out system, as the extra attention of lifting, potting, and getting the plants established would nearly counterbalance the labour of watering, which is the principal objection to the pot system. It is altogether different with plants like the Calla, where the size and strength of the leaves determines the size of the flower, as in the Salvia a well-furnished head of flower is of more importance than the size of individual flowers.—J. G.

NOTES ON AURICULAS.

Auriculas are plants well adapted for owners of small gardens, inasmuch as they take up but little room and are easily managed. No plant, indeed, is easier to cultivate, but they require considerable attention, and that, too, at the right time. Though natives of high-lying regions, where the air is clear and untainted by smoke, they will, nevertheless, thrive where less beautiful plants would pine and die. Amongst what are termed florists' flowers the Auricula is the first to gladden our eyes in spring with its rich and varied blossoms, and so popular has it become within these last few years, that the choicest and scarcest varieties are wholly unobtainable. The section of the genus which is most esteemed is that which was brought to a high state of perfection nearly a hundred years ago. Let me, therefore, briefly describe the points of excellence to which attention has so long been directed.

Green-edged Flowers.—The first class comprises green-edged flowers, and includes all that have the outer margin of the flower quite green, or very sparingly dotted with white points of meal, so that the edge at first sight still appears green. Inside this edge is the body colour; black is most esteemed, but it is also of different shades of maroon, violet, and plum colours; the body colour flashes into the edge, and is never found in a compact ring, as one often sees it in the "model" Auricula represented in drawings. If the body colour, as it often does, strikes through the outer edge, it is a serious defect, and the beauty of the best flowers is marred thereby. Next is the paste, which should be circular, dense, and pure white. The beauty of many otherwise fine flowers is marred by the angularity of the paste. The tube should be bright orange, as a pale tube quite as seriously mars the beauty of the flower as the body colour striking through to the outer edge. Beeston's Apollo is an example of a flower with a beautiful green edge, and the body colour and paste are also right, but its pale tube is a demerit, a fault even more strikingly exemplified in Trail's Prince of Greens. The beautiful emerald green edge of the latter incloses a perfect black body colour and solid pure white paste, but its watery tube ruins all. Auriculas, indeed, are still far from perfection as regards green edges, although many are very beautiful.

Grey-edged Flowers.—The next class is the grey edges, and in this are to be found the most perfect flowers yet raised. The points in this, as in the next class, are the same as those indicated above. The best flowers in this section have not the same defects as the best flowers in the green-edged class. Headley's George Lightbody, for instance, is an example of the very best Auricula in existence; its parts are evenly balanced, and the paste is circular. Lancashire Hero (Lancashire) is also a noble grey-edged flower, and one which is not always second to Mr. Headley's Masterpiece itself, though not quite such a decided grey as that flower; the meal, too, is so thinly laid on the edge, that it is sometimes classed with the green-edged sorts. A defect not yet mentioned, but one which cannot be overlooked, is a scollopy paste.

White-edged Flowers are distinguished from the grey by the greater density of meal on the edge. In some cases this is laid on so heavily that the edge is almost as white as the paste. This may be observed in Walker's John Simonite, a very fine flower, and perhaps the best white-edged flower yet raised. Yet another defect, and one most frequent in the white-edged kinds, is the body colour being dusted with the meal intended for the edge. Summerscale's Catherina, a small, neat flower, has this peculiarity; indeed, some varieties, such as Lightbody's Fair Maid, has this fault to such an extent that they cannot be tolerated in a select collection.

Selfs are flowers that have all the margin outside the paste one decided colour without shading, and they are necessary, having brilliant colours to form an effective contrast to the three other classes. Their edges are variously coloured, yellow, slate, bluish-violet, violet-purple, maroon, black, and crimson.

In Alpines the tube is yellow or pale as in the other class, but the part surrounding the tube is yellow or cream-coloured, and has no paste. This is surrounded by an edge of one colour which should be darkest near the centre, shading off to a paler colour at the edge. The finest Alpines are those with bright yellow centres and maroon or crimson-shaded edges. Flowers with cream-coloured centres have usually mauve or light purple edges shaded in the same way. There are Alpines with very richly-coloured edges or, as some term them, self edges, but they have a dull, heavy appearance in comparison with the shaded flowers.

Form of Trusses. — Auricula trusses should be well formed of five, seven, nine, and eleven flowerets or pips; even numbers do not fill in quite so well as odd ones. The truss should be supported by a stout elastic stem, long enough to carry the head of bloom bravely above the foliage. The diversity amongst the latter is very striking, and is at all times a source of enjoyment to Auricula growers. Some have the foliage quite as thickly dusted with meal as the flowers. Green-edged flowers, as a rule, have foliage destitute of meal. Many of the grey-edged sorts have mealed foliage, and some have it dusted with a very fine powder, and edged with a silver thread, as in Douglas's Silvia and Lightbody's Richard Headley.

Propagation.—This is effected by means of offsets, or by dividing the plants, and by seeds, from which alone new varieties can be obtained. Seeds should be saved only from flowers that have been artificially fertilised, and it may be worthy of remark that the pollen parent exercises the greatest influence on the progeny. Seeds may be sown as soon as they are ripe, or they may be kept until February, and sown in a gentle hotbed. If they be sown in July, when they ripen, the largest proportion of them will not vegetate until the spring. Some varieties increase much more rapidly than others, and many fine sorts remain scarce from the difficulty that exists as regards getting offsets. With the view of increasing scarce varieties, I have sometimes boldly cut their heads off near the surface of the ground. The top will make a strong cutting, and will soon form roots under a bell-glass, and the old stump will also soon throw out growths. I have obtained six or more in this way from one stump. Some varieties will not produce offsets so freely as others, even in this way. Lee's Colonel Taylor is very shy, but Taylor's Glory is quite the reverse; Cunningham's John Waterston is also a good breeder.

Careful potting is a prime element as regards insuring success; the drainage must be free, as stagnant water will cause the stems to rot. Cleanliness, too, must not be neglected. Greenfly, a troublesome pest, can be most readily destroyed by fumigating with Tobacco. It is best to do this during the winter; at other times the fly may be kept in check by brushing it off with a camel's-hair pencil. Decaying leaves sometimes induce the stems to decay if not promptly removed. During winter water must be applied with caution. I never water a plant until it is quite dry at the roots. J. D.

Coral-flowered Shrub (Berberidopsis corallina).

THE SHRUBBERY.

Berberidopsis corallina.—Amongst all the interesting and handsome shrubs which we have obtained from Chili, few, if any, surpass this in real beauty. It is of scandent habit, has glabrous, evergreen, spiny leaves, and long-stalked, deep crimson blossoms, which last a long time in beauty, and which are, moreover, produced in succession over a long period. It succeeds well in good fibrous loam, with a slight admixture of peat; and it has proved quite hardy in various positions, such as against a due south wall, on a western aspect, and also hanging over and creeping amongst stones on rockwork; in open situations, too, fully exposed all round, it succeeds about equally well. I am not aware how high it will grow ultimately and under very favourable conditions, but my opinion is that it will not much exceed 3 ft. in height, seeming to have rather a tendency to extend

laterally than upwards. Therefore, its proper position on a wall would be one of those bare spaces which one often sees between two other wall shrubs that grow wide at the top and leave the base bare. It is one of those really good shrubs for which a place should be made in every garden.—T. S. [The accompanying sketch of this valuable shrub was made in Messrs. Veitch's Nursery at Coombe Wood, Kingston-on-Thames.]

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

Jan. 17.—Sowing Agrostis nebulosa and pulchella in pots; also sowing a few rows of Little Gem Peas close to a south wall. Potting Masdevallias and Selaginellas. Re-potting plants of Calceolaria aurea floribunda into 8-in. pots for spring flowering. Putting in cuttings of Nasturtiums and Heliotropes. Putting in Vine eyes. Planting remaining fruit trees. Putting in plants to force for stands and cut flowers; also another batch of Asparagus. Shifting Humeas into 10-in. pots. Putting Asparagus tops over Peas just peeping aboveground to keep off sparrows, and to ward off frost; owing to the lightness of this material, the Peas grow right through it. Painting Apple and Pear trees with three parts lime and one part soot, mixed with water to the consistency of paint. Examining basketed Dendrobiums, and removing any decayed material. Watering Cucumbers, but taking care not to get them too wet. Sorting Apples and Onions. Making up hot-beds for Lettuces, Cauliflowers, Carrots, Raddish, tree Carnations, and Violet cuttings. Turning manure for Celery. Dipping Cinerarias into Tobacco-water for fly.

Jan. 18.—Digging Rose borders; also land for succession Peas. Sowing a border of Parsley, Carrots, Radishes, Alexandra and Paris Cos Lettuces, and Walcheren Cauliflower in frames. Potting some Tuberoses and placing them in heat to force. Putting in cuttings of Coleus, Crotons, and more Alyssums; also a little Musk in slight heat weekly. Nailing Roses on walls. Putting some red worsted over Peas that are coming up to keep off birds; also sooting Gooseberries for the same purpose. Finishing pruning Gooseberry trees. Thinning plantations.

Jan. 19.—Putting in cuttings of Ageratum and Solanum capsicastrum; also old plants of Achyranthes, Alternantheras, Heliotrope, and Mesembryanthemums into warm Vinery to induce them to furnish cuttings. Planting out Potatoes from pots. Getting all Roman Hyacinths in flower into greenhouse. Putting Kidney Potatoes into hampers to sprout. Cleaning scale off Camellias and one or two other plants. Making up hotbed for tree Carnation cuttings. Loosening shoots of Peach trees on wall ready for pruning. Clipping Privet hedges.

Jan. 20.—Digging vacant ground. Sowing Advancer and Laxton's Alpha Peas, Long-pod Beans, some Dutch Turnips, and Campbell's and Emerald Melons. Potting Mrs. Pollock Pelargoniums. Shaking out and re-potting Daturas and Erythrinums. Putting in more cuttings of Salvia patens, Fuchsias, Nepetas, Alyssum, Agathea, Achyranthes, and Coleus. Planting Seakale for forcing; also Potatoes as fast as they are ready for planting. Getting soil in to warm for potting French Beans. Tying pillar Roses. Forking amongst Gooseberry trees, giving them a sprinkling of guano. Removing suckers from fruit trees. Plants in flower—Yellow and other Roses, scarlet Van Thol and double Tulips, Crocuses, Mignonette, Deutzia gracilis, Monochætum ensifolium, Tydæas, Begonia incarnata, Lily of the Valley, Thyrsacanthus rutilans, Primulas, Azaleas, Dielytra, Hyacinths (red, blue, and white), Daphne indica, Calla æthiopica, Cytisus Attleeana and canariensis, Cinerarias, Camellias, Acacias, five kinds of Epacris, Erica gracilis autumnalis, and E. hyemalis.

Jan. 21.—Sowing Golden Feather Pyrethrum, Centaurea argentea, and more Mignonette in pots. Potting Kalosanthes into large 3-in. pots in very sandy soil, and placing them on south side of greenhouse. Putting and basketing Dendrobiums. Striking cuttings of Dracæna terminalis in strong bottom-heat. Planting more Potatoes in pits; also Ash-leaved Kidney and Myatt's under Peach wall. Liming and sooting the Gooseberries and Currants.

Jan. 22.—Sowing Cyclamen seed and putting it into cutting pit; also Auricula seed, and putting it into greenhouse; likewise a few Tripoli Onion seeds in heat, and Red and White Celery under glass on a manure bed. Potting Gardenias. Dividing Maiden-hair Ferns, and putting them into 3-in. pots. Potting some autumn-struck Fuchsia cuttings. Layering Tree Carnations. Nailing Apricots. Covering Celery with straw to protect it from severe frost. Top-dressing Orange trees with half manure, half loam; also Lilacs and Laburnums. Making up Potato beds for frames. Putting soil in to warm for young Cucumber plants, and getting leaves and other fermenting material in pit ready for them.

Glasshouses.

Climbers.—Where plants for draping the rafters, covering an end wall, or for using in any similar way, are employed in the stove, they should now be gone over and cut back sufficiently according to their kinds. In carrying out this operation it is necessary to proceed with discrimination, using the knife the most freely on the strongest-growing subjects, that soon extend so far as to injuriously encroach upon other plants. Strong-growing climbers, such as Ipomœa Leari, Bougainvilleas, Dipladenias, Thunbergias, Clerodendrons, and the large-leaved Passifloras, may be freely cut back proportionate to the size of the plants and the space they are intended to occupy, remembering that in all cases the further they can be allowed to extend, the more profusely they may be expected to bloom. Medium-growing climbers, such as Combretum purpureum, Ipomœa Horsfalliæ, Jasminum Duchesse d'Orleans, the double and single varieties of J. Sambac and Manettias, should not be so hard cut in.

Stephanotis floribunda ought not to be cut back to any considerable extent at this time of the year. What pruning is necessary should be deferred until after the flowering, when all the shoots may be shortened in accordance with the space required to be occupied. Supposing the growth to have been well ripened during the preceding autumn, reduction of the shoots now will proportionately limit the abilities of the plants to bloom.

Hoyas.—The twining species of these should only have their shoots shortened either at this or any other time of the year, so far as is necessary to keep them within bounds; for flowering, as is their natural habit, during a series of years from the same spurs, whatever reducing of the shoots is carried out in their case also limits the blooming. In cutting back all the above plants it is necessary for the operator to pay some attention to carrying the work out in a way that will admit of the production of young growth over the whole surface which is retained of the plants individually. This can only be effected by shortening the shoots to different lengths in place of, cutting the whole back to something near a uniform length, the result of which is that nearly all the young growth made is from the point where they were shortened back to, leaving the lower portion of the branches devoid of fresh shoots, and, consequently, unable to bear flowers, of which it is desirable that an equal production over the whole surface of the plants should exist.

Fine-foliaged Climbers. — Climbers that are grown for the beauty of their leaves, such as the different species of Cissus, Pothos argyrea, Echites nutans, &c., should be freely cut back, so that the greater portion of the surface they occupy during the summer may be covered with new foliage. It may be well here to remark that the time of cutting in gives the best opportunity during the whole year for giving a thorough cleaning from insects. With these plants it is necessary now to do all that is possible to eradicate these pests, as from the position occupied when growth has fairly commenced there is less opportunity of dealing with them than in the case of non-climbers.

Fine-leaved Plants.—There is no greater mistake committed with these subjects than allowing them to get so tall as to be deficient of healthy foliage at the bottom, or in any way to exhibit old leaves wherein is an absence of the fresh, healthy vigour and colour for which they are grown. We often see plants like Dracænas, Aralias, Brexia chrysophylla, Crotons, Cupanias, Ficus, Sphærogynes, and Cyanophyllums in anything but a condition that makes them pleasing objects, for want of heading down when they require it. Now is the best time for this operation, in all cases allowing the soil to become somewhat dry before removing the head. With strong-growing species, such as Sphærogynes and Cyanophyllums, that process a limited number of eyes, it will be found much better to leave from 2 ft. to 3 ft. of stem, cutting the eyes out from the top downwards to within 6 in. of the collar; this will force their breaking near the base, which will insure a handsome stem, well furnished with leaves down to the bottom, and by leaving a considerable portion of the stem in this way, until the young shoot which is to form the future specimen has made some progress, it will materially assist the young growth, and avoid the chances of the cut-down plant dying, which sometimes results from the whole of the head and stem being removed at once. Plants treated as described should always be placed immediately where there is enough warmth to induce their breaking without delay, as, if kept where so cool as to retard growth, the inevitable loss of roots consequent upon heading down is certain to be further increased; to this frequently may be traced the death of the plants. The headed-down specimens ought to be syringed daily, taking care not to wet the soil too much until they have commenced to grow freely.

Gloriosas.—When these plants are grown, either as trained specimens or pendent from a rafter, place the bulbs at once where they will start into growth, as they take a good time from the young shoots beginning to push to their arriving at a blooming condition, and it sometimes happens that when the growths are not made sufficiently early, it gets far towards autumn before they flower. It is better not to give them too much pot room in the first instance. They succeed more satisfactorily by potting a second time than at once placing the roots in the full body of soil they are to occupy.

Ferns.—Structures devoted to the cultivation of Ferns have usually at the present day more or less space so arranged that the Ferns can be planted out, giving them so far as possible a natural appearance. In the selection of the plants to be thus treated it is necessary to keep in view the suitability of the kinds chosen for the purpose, both as to their ability to bear shade proportionate to the position each individual plant will occupy by being overhung by others, and also to the size they will ultimately attain. It frequently happens that a want of consideration in this last matter much interferes with their well-being afterwards by some encroaching upon others, which either necessitates disturbance by removal, or a portion are so weaked by overcrowding that they ultimately die. The greatest mistake where Ferns are so grown is the introduction of too many large tree species that inevitably smother most of the weaker small growers, and in a few years have not near enough space for their own development. When many specimens of large habit of growth are brought together in a comparatively small house, it not only detracts much from the individual beauty of each, but destroys the effect of the whole; unless where the house is large and roomy in every way, it is better to have the tree kinds in either tubs or pots, plunged up to the rims in the beds where the smaller growers are planted out, by which means they can be kept within the prescribed limits, at the same time allowing them to develop sufficiently to exhibit their true character. Another advantage arising from their being grown in this way is that the position of any particular plant, or the whole of the large ones thus grown in tubs, &c., if need be, can be altered as occasion requires, either with a view to afford more room where it may be wanted, or to give a different appearance to the house where a continuous position held by the plants is somewhat monotonous. The present time, when most Ferns are at rest, or nearly so, is the most suitable for any alteration required in the arrangement, as the smaller occupants which are planted out, some of which there would be a necessity for moving, can be taken up and replanted where wanted without seriously interfering with their growth, which removal later on, when their young fronds have begun to push, is certain to do.

Insects.—Here also advantage should be taken of their dormant state to eradicate the insects most usually troublesome—brown scale and thrips. Scale is not easy to cope with on Tree Ferns that are planted out, and unless an attempt is made now when the insects are not increasing fast, and the fronds are in a hard mature state, which enables them to bear a much stronger dressing of insecticide than during the growing season, a deal of labour will need to be expended upon them in summer. The eggs of thrips can, in like manner, at this time, be more effectually dealt with. The best way to proceed that I have been able to find is to dip the fronds singly in a strong solution of insecticide, allowing it to dry on, repeating the operation three or four times before the young growth commences to move; any old fronds that show signs of decay may be cut off, and in this way whatever insects are on them will be got rid of.

Flower Garden.

Carnations and Picotees.—Soil for potting ought to be prepared; good turfy, clayey loam answers best. The decayed turf should be torn to pieces by the hand, carefully inspecting it at the same time with the view of destroying all the wireworms which it may contain. To four parts of loam add one of leaf-mould, one of rotten stable manure, and one of sharp sand, mixing all together by turning the

mass over twice ; it ought then to be stored in a dry place until it is required.

Dahlias and Hollyhocks. — If the weather is unfavourable for other work, stakes may be prepared. Those made of good deal, and painted green, last the longest, and look the neatest. The part underground and a little above it should be dressed with a composition of equal parts of tar and pitch laid on boiling hot ; even charring the part of the stick that is to go underground tends to prevent decay.

Pansies and Pinks.—Those in beds will require attention during alternations of frost and thaw, as it is at such times they get injured. Dress the surface of the beds with dry manure from a spent Mushroom bed, which is about the best material that could be used for preventing injury during changeable weather.

Phloxes in Pots.—Plants that were raised from cuttings, and that flowered last autumn, should now be placed, if possible, in a greenhouse temperature. Growth will thus be made earlier, and the cuttings can be taken off, perhaps a month sooner than it would be possible to do if the plants were protected only by a cold frame. It is rather too early as yet to repot, but that operation might, nevertheless, be performed now, if it be likely that the pressure of other work would prevent its being done a month or six weeks later. The potting material recommended for Carnations answers well for Phloxes.

Fruit.

There are sundry little operations which may be done now with advantage, such as labelling any trees requiring attention in that way, cutting shreds for nailing, or preparing matting for tying, as the case may be ; cutting and pointing stakes for newly-planted trees, preparing the necessary spring protection for wall trees, and repairing netting. The fruit room, too, may be overhauled, and all decayed Apples and Pears removed. Some of the latter that are specked are apt to become mouldy ; these should be wiped with a soft, dry cloth. Easter Beurré is very subject to this mould, and, to keep it sound, it requires to be thus wiped several times in the course of the winter. Josephine de Malines, Ne Plus Meuris, and Easter Beurré are our best Pears at this date.

Vegetables.

A hot-bed consisting of three parts leaves and one of stable litter should be made up for Potatoes, on which place frames, and plant the Potatoes at once in about 9 in. of light soil. Fenn's Early Market (round) and the old Ashleaf Kidney are the best kinds for the purpose. A similar frame should be put in requisition for Early Horn Carrot, and another for Lettuces, Radish, and Cauliflower. Asparagus shonld be introduced to the forcing pit every fortnight. The crowns now start readily into growth, and a great heat is therefore unnecessary. A bed of leaves only is the most desirable forcing medium, as stable litter taints the Asparagus, especially when that material is used without due preparation, and the same may be said in reference to Rhubarb. If the crowns of these be now covered with Rhubarb pots, old tubs, or barrels, and a bed of leaves made over them, there would be an abundant supply till it could be had from the open air. Seakale is best lifted and forced in any dark, warm situation ; a Mushroom house suits it well. It should be kept perfectly dark and not too warm, or it grows thin or weakly. It may also be forced the same as Rhubarb in the open ground, but preference should be given to the system of lifting it. To keep up the supply regularly, fresh roots should be put in fortnightly. French Beans are always prized, and where there is proper accommodation for growing them they can be produced in abundance without much trouble. They should be grown in light houses or pits where a temperature of 65° can be maintained. They are best in 8-in. pots, which should have free drainage, and the soil should be light, but made firm in the pots. A moist atmosphere is indispensable both for the well-being of the plants and to keep red spider at bay. Sow, to keep up the demand, at intervals of ten days or a fortnight. Syon House and Osborn are the two best kinds for pot culture ; stick them with Birch twigs before they begin to flower, and never let the Beans stay on the plants an hour after they are fit to gather. Tomatoes (autumn-sown plants or cuttings) will now begin to grow freely, and will require a warm, dry temperature of from 60° to 65° to set the fruit, after which they may be freely supplied with tepid guano water, of which if well drained they will take a liberal allowance. Pot culture and winter forcing of Tomatoes are not nearly so much practised as they ought to be. By many no forced vegetables are more valued, and from the present time onwards are more easily produced. Lettuces and Endive under protection must be kept as dry as possible, or they will soon decay ; Chicory and Dandelion help to eke out the Lettuces and Endive, and a few roots of these should be placed for forcing in the Mushroom house every two or three weeks. Mustard and Cress should be sown weekly.

WINTER COVERINGS FOR GLASS STRUCTURES.

A FREQUENT occurrence of severe winters would undoubtedly have the effect of inducing plant growers to adopt some efficient system of covering their glass structures in frosty weather. Not only do coverings, even when of a slight description, effect a considerable reduction in the coal bill, but their application renders it a more easy matter to maintain that moist, genial atmosphere so necessary to the well-being of many kinds of tender plants during the winter season. There is also a great advantage in being able to exclude frost during the early part of the winter season without having recourse to fire-heat, the application of which, even when the greatest care is exercised, is apt to exercise a stimulating effect upon plants which it is desired should fall into a state of complete rest before the advent of the shortest day. In Germany and Switzerland, where severe winters are the rule, a system of covering glass houses and frames with straw mats and boards prevails ; and those growers who may have unheated structures to deal with, and amateurs who find the constant watch for frost and the frequent lighting of fires and late night attendance rather irksome, might with great advantage adopt this method of covering. I fear that the owners of cold frames have often in the spring a pitiful tale to tell of plants destroyed or much injured, in most instances arising from want of efficient protection. In the first place, frames should be well protected at the sides ; to effect which as soon as the plants are housed drive in some stout stakes about 1 ft. from the brickwork and 9 in. apart. Nail on to the top of them a piece of inch stuff on another piece about half way up the stakes. Stuff the interstice with any Fern, ramming it down tightly and covering with a board, so as to shoot off heavy rains.

The Bracken being thus preserved in a dry state throughout the winter, there will be but little need to fear the most severe frost. Litter is often used for covering the glass, but its use generally entails a certain amount of breakage ; and then again it is sure to get dirty, in which case the glass becomes more or less smeared, and the inmates of the frame fail to get the amount of light necessary to maintain them in health. The Germans, even in their severe climate, do not hesitate to confide such tender subjects as the Cineraria to the protection of cold frames, and some of the best plants I ever saw were wintered in unheated structures, which had to resist continued nightly frosts of 30°. In the first place, neat straw mats are laid upon the glass, and these are covered with shutters some 4 ft. in width. To one side of each shutter is nailed a strip of board in such a manner that it overlaps the shutter placed next to it. In this manner not a drop of rain can penetrate, and snow is quite excluded, with the consequent effect of keeping the mats quite dry. In a general way only the boards are needed, as when the sides are well protected they will exclude 10° of frost. In very severe weather either the mats may be doubled, or litter of some kind may be placed on the boards. The advantages of this method are that there are but few days when the frames may not be uncovered, the coverings need not be put on so early, and the glass is preserved in a clean state. Houses are covered in much the same manner, only that a narrow board has to be placed in an upright position on the weather board to catch the covering boards, and another narrow board or piece of galvanised iron is fixed in such a manner to the ridge board, that the shutters just run up under it. These latter are, however, light boards, fitted in the same manner as described in the case of the frame shutters.

For small houses, where the roof comes near the ground, this method of covering would prove very useful, and small growers by adopting it would find themselves relieved of a considerable amount of labour and anxiety. Having had considerable experience in this system of covering, I can confidently recommend it, and feel certain that, especially in the case of frames, any one once adopting it would never willingly relinquish it. Having referred to straw mats, a few words as to their construction may not be out of place ; for although bass mats may be employed, they are not nearly so warm as those made of straw, and are in the long run more expensive. Take two stout pieces of quartering, about 1 ft. longer than the frame. Nail a stout piece of stuff, corresponding in width of the frame, in such a manner that a framework the same size as the sash is formed. One piece should be nailed, so as to come flush with the ends of the side pieces, this portion of the framework coming uppermost. Into these pieces drive stout nails 6 in. apart, and nail another slip of wood diagonally across the framework, which will keep all in place. The frame being thus formed, a strong cord has to be stretched from the nails at top to those at the bottom, and a stout short piece of stick with strong twine wound round it is fixed to each one. Then, taking about five straws in the left hand, lay them athwart the strings, the butt ends outwards, and passing the twine to the left of and round the cord in such a manner that the stick may be passed between them, thus forming a running loop which, being tightly drawn, fixes the straw firmly in place. Beginning at one end, fix the straw to one half of the cords in the manner described, and then with other straws, again placing the butt ends outwards, work through the remainder of the strings. By continuing in this manner a neat mat of uniform thickness will be formed which will keep out 10° frost, and which with care will last some years. There are other methods of manufacturing straw mats, but none so good as that here described. French growers largely use these *paillassons* and utilise wet days and severe frosty weather for making them. Rye straw is the best for the purpose, in default of which good hand-threshed wheat straw may be used. Never employ machine-threshed straw, as, owing to its being so broken, it absorbs and retains much moisture and soon wears out. When the mat is finished the sides must be trimmed, which is best effected by laying them between two stout pieces of board in such a manner that about an inch of straw projects, which may be neatly and easily trimmed off with a sharp knife. Those who can grow straw expressly for the purpose would do well to do so, as if cut just before it is ripe it is much tougher and consequently lasts much longer than when the grain is allowed to mature.

Byfleet. JOHN CORNHILL.

HARDY FLOWER GARDENING.

IF I understand a recent query aright, it is wished to maintain a series of flower beds in a gay effective condition from early spring till the end of July by the aid of hardy plants above, and this desired end it is proposed to attain either by means of such subjects as will bloom freely throughout that period, or by substituting for the spring flowering plants when their blooming season is past others which will flower during the early summer months. Now there are a few hardy flowers, such as the bedding Pansies and Violas, which bloom freely from early spring till late in summer, and if your correspondent merely wishes for a gay garden, these would sufficiently answer his purpose ; but I surmise that variety is sought for, in which case I should suggest a compromise, employing both spring flowering subjects and such as bloom at the desired time in summer, but planting them permanently, and rejecting altogether the double shift idea, which in the case of hardy plants involves the expenditure of much time and labour, and is not at all likely to be satisfactory, for all hardy subjects in order to give good results should have good

hold of the soil by April. In the first place I would advise that the centre portion of two beds be planted with early-flowering Clematis—one to consist of rubella, which, although of the Jackmani section, comes into flower by the middle or end of June and is rich claret purple, and Fortunei, creamy white, alternately. The Clematis should be planted alternately some 18 in. apart, and in the angles formed by them bulbs of Tulips and any of the early flowering varieties of the Gladiolus, such as Blondus, Colvilli, cardinalis, &c., might be planted, these of course to remain a fixture, for the annual top-dressing necessary for the Clematis wouldserve to maintain them in vigour; and these early-blooming Gladioli are much hardier than the late flowering kinds, and may be relied on to last and increase in vigour and beauty. Next to the Clematis might be planted a row of white and yellow Pansies alternately, such as Vestal and Golden Perfection, two excellent continuous free-flowering, effective kinds. The outer circle might consist of any pretty dwarf spring flower, such as the Gentianella, and Snowdrops might be freely dotted in here and there between it and the Pansies. The centre of another bed might consist of Clematis of the Florida type, such as Countess of Lonsdale, Lucie Lemoine, and John Gould Veitch, which bloom in June and July. Between these we would plant single Hyacinths of colours and Gladiolus ramosus and cardinalis, planting outside them a ring of Viola Blue Bell, and finishing off with Polyanthus and Crocus. With the exception of the Violas and Pansies, which would require to be fresh planted every autumn, these two arrangements would be permanent, and would render the beds gay from early spring till late in summer.

Hyacinths and Tulips.—These would come into bloom before the Clematis made sufficient growth to hide them, and they would be far on the road towards perfecting their foliage by the time that they became much shaded. The Clematis should be trained to sticks some 12 in. in length, inserted crosswise in the soil, and the training may easily be so conducted as to afford to the Gladioli the amount of light necessary to their well-being. Light-coloured Clematis and bright-tinted Gladioli make a fine contrast, and the latter get from the Clematis a certain amount of shelter and support, and do not become so much beaten about as when standing alone. I have seen some very pretty arrangements in this way, but I would not counsel the employment of the choice hybrid kinds, but only the more robust varieties, such as will stand without injury the vicissitudes of our English climate. One bed I would plant with double Pyrethrums, which flower so freely during May and June, and amongst them I would plant freely Daffodils, edging the bed with Aubrietia græca. It is a pity that your correspondent has so great an objection to the use of Lilies, as the early flowering kinds might be used with excellent effect. There is nothing, for instance, much better in the way of a floral display than a good bed of crimson China or Cramoisie Supérieure Roses, from which spring forth numerous flower-spikes of the old white or orange Lilies. The Roses afford some protection to the Lilies, and unless these latter are much exposed to the fury of the wind, they will when thus situated need but little support. In any case, however, the labour of staking is not very great, and the Lilies are so distinct and beautiful, that a little extra time bestowed upon them is not misspent. To obtain a true idea of their beauty, several bulbs should be planted together. This arrangement is one that needs no remodelling with each recurring year; a bed thus made will, if annually supplied with nutriment in sufficient quantity, last in unimpaired vigour for four or five seasons. Still, another combination might consist of

Hardy Annuals. Of these, such as Collinsia, Clarkia, Nemophila, Leptosiphon, &c., may be sown in autumn, as also English and Spanish Iris. The annuals would come finely into bloom during April, May, and on into June, and would be succeeded by the Iris, which would about fill out the required time. Such an arrangement as this would necessitate the yearly renewal of a portion of the plants, and the soil would have to be well stirred to admit of the annuals coming to perfection. These latter should be sown early in September and placed where they are to bloom by the latter end of October at the latest. J. C.

Aquatic for Small Pond (the Variable Arrowhead).—This very elegant Arrowhead (Sagittaria variabilis) is a native of North America. Some of the leaves of young plants are long and narrow without any lobes at the base, and in the lobed ones the divergent lobes are nearly of the same form and size as the terminal portion of the leaf. The leaves are from 6 in. to 12 in. long, according to the vigour of the plant, and the flowering scape from 1 ft. to 3 ft. high. Messrs. Henderson, of the Pine-apple Nurseries, have introduced and are cultivating this variety in small tanks and ponds in their nursery. A variety called gracilis is a miniature of the foregoing, usually about 1 ft. high, with exceedingly narrow leaves on relatively long stalks. For small ponds or tanks in Ferneries, greenhouses, or in the open air this

Various-leaved Arrowhead (Sagittaria variabilis).

plant is well worth securing, as, in addition to its pretty white flowers, its variably formed leaves are very interesting.

VEGETABLES.

Mushroom Culture.—Provided that the materials are at command, nothing can be simpler than Mushroom culture. The best and most lasting material is two-thirds horse droppings and one-third of light loam. The manure should be had fresh from the stable, be thrown together to heat, and the soil spread over and intermixed with it. Turn it over each day for a week to allow the obnoxious gases to escape, and the soil to get thoroughly incorporated with it. At the end of that time it may be formed into a bed, which should be as firm as possible by treading or beating as the work proceeds, and it should be at least 2 ft. in depth. Bottom-heat thermometers or test sticks should now be put into the manure, and when the heat has declined to 75° the bed may be spawned by dibbling into it, 2 in. deep and 9 in. apart, pieces of spawn the size of a bantam's egg; then beat down the surface and cover the whole with good light loam to a depth of 2 in. If, however, there be any danger of the bed re-heating above the 75° named, the soiling had better be deferred till that danger is past. The bed should now be covered up with a thin layer of straw or long litter, over which lay mats; and no watering will be requisite till the Mushrooms make their appearance. Provided the temperature of the house does not go lower than 45°, fire-heat should not be applied; should it get lower than that, employ slight fires, and neutralise their drying effect by occasionally damping the floors and walls. To prevent the depredations of woodlice, procure a couple of toads and encourage them to stay in their lodgings by furnishing them with a saucer of water at which they can drink. Under the above treatment Mushrooms should make their appearance in about six weeks; and if the weather be bright and drying, water may be required, but, as a rule, unless the bed seems very dry, it is best not to water till the Mushrooms appear. An arid atmosphere and over-watering of the beds are fatal errors in Mushroom culture.

A Cottager's Experience in Growing Potatoes.—"Burns" (p. 510) says my remarks on this subject in a previous number are misleading, and wishes for an explanation. I will give it as well as I can, but first I would say I was in the north on July 31, and I noticed how well the Potato tops looked when ours here were most of them black with the disease. My soil is light with gravel beneath; the situation cannot be better; it is in a field away from all houses, smoke, &c.; it lays high enough to keep all wet off except rain; still we had the disease very bad; the cultivator would have been clever if he could have prevented it. After the many years' experience that I have had in growing vegetables for exhibition, I do not think I must be put down as a novice; I think I know the benefits of changing seed and situation. To the two sorts I mentioned as a failure I ought to have added Fenn's Bountiful, which was equally as bad. Now, the situation where these grew had no Potatoes grown on it for at least six years. I followed the instructions given in GARDENING, January 31, 1880 (p. 739). The ground was thrown up rough until the time for planting, then it was forked over and the Potatoes put in the trenches and covered up, and was not walked upon until the crops came up. Now for the Roses. I must inform "Burns" and his neighbours that I have seven different sorts in good cultivation, and the following are a few of the varieties of other flowers that I grew last year: Asters, French and African Marigolds, Stocks, Carnations, Phloxes, Verbenias, Pansies, Coreopsis, Geraniums, Lilies, Everlastings, Heliotropes, Golden Feather, &c. The cause of our failure we attribute to the wet season with so much thunder and lightning. I say we, because a great many had the same painful experience as myself, professional, amateur, and cottager.—T. S.

The Law Relating to Greenhouses.—Your correspondent "G. W.," in GARDENING ILLUSTRATED (p. 533), appears to me to omit what is a material part of sec. 157, 38 and 39 Vic., cap. 55. The full section is "with respect to the structure of walls, foundations, roofs, and chimneys of new buildings for procuring stability and the prevention of fires and for purposes of health." Further, I do not see that it is at all clear that the buildings contemplated by the Act mean buildings intended for habitation. On the contrary, sec. 159 refers to the case of "conversion into a dwelling house of buildings not originally constructed for human habitation." It is possible that a careful examination of the Act might throw further light upon the subject. The two points I have referred to seem to me rather to point to the conclusion that a greenhouse as ordinarily constructed would be held to be a building within the meaning of the Act, and I think that this would only be reasonable when it is considered that the Act is intended to guard against the erection of buildings that might be a source of danger either from defective construction or from risk of fire.—P. G. C.

Substitute for Small Pots.—We have often read of thumb pots for plants. An egg shell is a very inexpensive one, and answers its purpose well; break one end a little larger than you do the other, making simply a small hole; then fill with earth, and if you wish to put plants in them, set in a box the height of the shell; fill the spaces with earth; the plants start splendidly, and can be taken out and handled very easily. As the shells are much lighter than pots, they are more desirable for

shipping; fill the space with moss or any light substance used for that purpose.—*American Paper.*

HEPATICAS.

THESE are among the most charming of spring flowers. They will grow in almost any position in the garden and they are admirably suited for growing in pots for the window or greenhouse. They are perfectly hardy, easily managed, and cheap, and if kept free from weeds and liberally supplied with water, so that plenty of foliage is formed, a fine head of bloom will be the result. The most suitable sorts are the single white, blue, and red, the double red and blue, and the well-known pale blue angulosa. It is the nature of the Hepatica to strike its roots down deeply; consequently plants of it seldom succeed in a shallow soil, and never in a dry, hot one. The hardest frost or the most searching cold does the plants no injury.

Propagating.—The way Hepaticas are chiefly increased is by division of the roots, and in this way they are readily propagated, and immediately after blooming, just when the plants are actively engaged in the production of leaves, is the best time for the operation. If well rooted, single eyes will make good plants by the following season, and they should be planted in a bed of deep and rather light loam, which should be in a position accessible only to the morning sun. Hepaticas are plants which will also repay the trouble of raising from seed, as thereby a great variety of colour is gained. The seed does not germinate till the following spring, but it should be sown when ripe. Turfy oam mixed about half-and-half with Cocoa-nut fibre is the best compost for sowing all such seed as will have to remain a long time in the pans; this compost does not become sour or consolidated. The pans may be placed in any cool frame or greenhouse, and the soil must be kept just moist. They should not be exposed to the sun, but should have a moist shady place so as to prevent the soil having to be often watered. Some growers recommend that the plants should be parted not oftener than once in three or four years, as frequent divisions are apt to weaken them and cause some to die.

In Pots.—Strong established plants of Hepaticas in pots will flower earlier than similar plants in the open border, and, at a time when all kinds of flowers are scarce, it is well to have some under glass, as they are thus kept from rain and frost, and preserve their freshness and beauty for a long time. When once established in 6-in. or 7-in. pots they should be occasionally top-dressed, but not too often re-potted; the greatest check, however, is given when a plant has so increased in size as to render division necessary. It is, in this case, best to divide sparingly, say into three or four divisions, and these, if re-potted at once, soon become re-established. Small plants should be potted into 3-in. pots, and in these they may remain the first year, plunged in ashes in a shady situation for the summer. The next year they may be shifted into pots a size larger, and so on until a size sufficiently large is reached. The Hepatica is closely related to the Anemone.

The great Hepatica (H. angulosa).

FRUIT.

CULTURE OF FIGS.

WANT of knowledge of the mode of bearing and habit of growth of the Fig has often ruined the prospects of a crop under orchard house or open wall culture. Forced with artificial heat, which enables us to extend its season of growth from January till the end of October, the shoots of the Fig may be pinched at every third or fourth joint three or four times during the season, and each pinching will ensure a crop of fruit; but the same practice applied to plants growing in cool houses or out-of-doors would be simply ruinous, as far as the fruit was concerned. Under the latter circumstances the first essential is a well-drained and not too ample border, composed of good garden soil or loam, to which may be added plenty of lime rubbish, the whole made tolerably firm, in fact hard. The Fig is one of the most vigorous rooting fruit trees we possess, and in this climate, if the roots are not more than usually kept in check, fruit cannot be expected. At the same time, we should prefer giving the trees a narrow and shallow border, to be filled with roots that will be allowed to remain undisturbed, to frequent root-pruning. The fruit of the Fig is exceedingly apt to drop if the trees experience any check, such as root-pruning is sure to produce, however carefully done; and the safest plan is not to reduce the number of the roots, but to place them in such circumstances that they are completly under control as regards feeding. The permanent fertility of a Fig tree so confined is perfectly surprising, and it is this fact upon which the

Pot Culture of the Fig is founded. We have seen plants, from which not more than one good crop was expected in the season, that had not been shifted for ten years, yet they bore well, being well fed. We turned one such plant out by breaking the pot, to which the roots adhered so that no tapping would disengage them, and found that the soil had almost disappeared, the pot being filled completely with a mass of roots, that had warped themselves round and round it till they threatened to rend it asunder. Yet the application of top-dressings, water, and occasional doses of liquid manure was all that was necessary to sustain the plants in health and to enable them to produce good crops of fruit annually. Such facts as these should be noted by those who attempt the cultivation of the Fig outdoors in this country.

In Orchard Houses the trees should be kept in roomy tubs or large pots, which should be plunged, but care should be taken that they do not root through the bottom into the border, which they are likely to do if they can find a hole or crack anywhere. The rapidity with which they will develop when once they escape in this way is marvellous, and will generally be indicated by barren shoots of corresponding vigour in the tree.

Borders for wall trees 12 ft. or 18 ft. in height need not exceed 6 ft. or 8 ft. in width, nor be deeper than 18 in. The bottom of the border should be of concrete or paved, or, at least, rammed so hard as to be impenetrable to roots; this is practicable if the sub-soil is somwhat strong and adhesive. Of course the sub-soil should be dry, and drained if necessary; but for a border of such moderate dimensions a regular bottom of drainage, as in Vine borders, is not necessary. A single row of 4-in. tiles along the front of the border will ensure the removal of all stagnant water readily enough. To prevent the roots from extending beyond the limits of the border, a 5-in. brick wall of the depth of the border should be carried along the front. This will effectually bar their progress, and is a better and more certain plan than chopping the roots off annually with the spade.

Pruning and Training.—Outdoors, or in orchard houses, only one crop of Figs is produced in the season, and the fruit is formed on the wood of the previous year near the points of the shoots; consequently, pruning must be conducted with the view to the equal distribution of the annual shoots, which must on no account be stopped, otherwise the embryo buds which form in the axils of the leaves, and attain the size of small Peas by autumn, will be forced to swell prematurely; and if they do survive the winter, it will only be to drop off the summer following. With standard bushes, therefore, the best plan is to allow the shoots to grow without stopping till the end of the season, only thinning them out in good time to admit the light to those which are left, that they may be well ripened. With wall or trellis-trained trees the same treatment applies, only that space may be saved by tying such shoots as are retained to the naked limbs about the middle and bottom of the trees. There are several methods of training Figs, but it is not of much

consequence whether the horizontal or fan system is adopted so long as a good supply of young bearing wood is laid in annually. We have seen wide and lofty fan-trained trees in which not a foot of space was left void of bearing shoots. The foliage of the Fig is so ample that there is much danger of crowding when the trees are trained against walls. The shoots should therefore be thinned out freely where they appear to be too thick, and they must not be tied in too closely during the growing season, but allowed to project from the wall, so that the points of the shoots may be exposed as much as possible to the light, as on the full development of the leaves near the top of the shoots depend the quantity and quality of the fruit. If summer pruning and training have been conducted properly, little or no pruning will be required in winter. It will only be necessary to tie the shoots in finally in as easy positions as practicable, giving the points liberty, that the young Figs may not be rubbed or squeezed when they begin to swell the following season.

Protecting, Watering, and Mulching.—When tying-in is finished the trees should be protected from frost by hanging mats, Fern, or Spruce branches over them. It will also be better if the border is protected from excessive wet during the winter. The shoots will not suffer if permanently matted up from November till March; but though the Fig does not begin to grow till May, or later in this country, the protecting material should be reduced or removed daily as soon as the sun's influence begins to be felt in spring. The border, also, especially when it gets well filled with roots, should be mulched, and during the summer water must be given in abundance when required. The Fig is a prodigious drinker, and the fruit is sure to drop at the critical stage if the trees are allowed to suffer from drought at the root.

Other culture during the bearing season consists in keeping the shoots regularly and thinly distributed, and exposing the fruit freely to the sun and air. To prolong the Fig season the custom is, as we before hinted, to force the trees and induce second and third crops by the systematic pinching of the shoots. But it is a question worth solving whether an equally long supply of fruit of much better quality could not be had by adopting orchard house treatment, the extention system of training, and by employing varieties that ripen their fruit in succession. For my own part I consider that the habit of the Fig tree and its mode of bearing point to the standard form of training as best adapted to it, and that it is undoubtedly the best way to grow it in orchard-houses, where, by adhering to the simple plan of thinning, but never shortening the shoots, heavy crops of fruit might be calculated upon to a certainty every year with such a sure bearer as the Fig tree.

S. W.

ANSWERS TO QUERIES.

3653.—Chinese Miniature Plants.—Lord Amherst in an account of his embassy to China, undertaken about a century ago, gives a description of the plan adopted by the Chinese to secure miniature fruit trees, which plan would, I suppose, be applicable to all other trees, plants, and shrubs. As far as I can remember, and briefly it is this: A suitable branch giving good promise of fruitfulness having been selected, a quantity of light soil is placed around its stem some little distance above its union with the parent trunk; this soil is kept in its place by means of a coating of clay, which is further secured by pieces of rag or other such material bound around it, and the whole is kept constantly moist. This induces roots to form from the stem of the branch into the soil, the branch of course in the meantime receiving its nutriment through the parent trunk in the same manner as the other branches not so treated. When the roots are sufficiently strong the branch is severed from the trunk just below its newly formed roots, the rag and the greater portion of the clay is removed, and the miniature tree is then potted, and has thenceforth to fare for itself. If this operation is commenced before the blossom has fallen, the branch will be ready for removal from the trunk before or about the time the fruit has ripened; and it is, I believe, claimed that the fruit will hang longer upon these rooted scions than upon the parent tree. It is some years since I read this description, and cannot just now give further details, but if desired I shall be happy to supply them after a reperusal of, or reference to, the book in question, which is now rather scarce.—A. J. KENT.

3932.—Gas Lime in the Garden.—This is in my opinion the most useful of any waste that can be applied to land. I have used it for several years and find it to answer remarkably well for any kind of soil. On light soil it eradicates all kind of insect pests, such as worms, slugs, &c., and on calcareous soils it assists the soil to produce much larger and better flavoured vegetables; whilst on cold, heavy, damp soils, the effect is much quicker produced than on any other soil, as its stimulating and forcing properties are equal to nitrate of soda. Beside its calcareous qualities, the ammonia, or volatile alkali, is a substance which quickly neutralises and enriches the soil; it is, therefore, as good a fertiliser as I know of. By the way I will remark, that if anyone wishing to make the experiment, get a quantity of gas-lime fresh from the purifers, and let it lay together protected from the wet, so as to allow the ammonia to concentrate together. After laying together for a time, lumps of ammonia will be found, so that it will at once show the qualities and properties of gas-lime. No one need be afraid to use gas-lime in a garden where they want to grow really good vegetables or root crops, but I must say that it should not be put on ground near the roots of trees, say not within 4 ft. of the stem. The plan I adopt is to dig over the ground, and then spread over the surface as much as will cover the ground. Another plan I adopt is to get a few loads of lime, bottoms from the tanyards, and about the same quantity of gas-lime, and mix up all the weeds and rubbish from the garden. After laying together for some few months, turn it over and mix well together, and then it will be found to be quite harmless if put on ground to any crop. I have used it on Grass land, and find it to answer satisfactorily, but I would caution anyone against sowing seeds for a few weeks after putting fresh gas-lime on the ground; but the mixed heap may be used as advised, and the seeds sown at once. November would be the best time to use the lime in the raw state. Fork over the ground in the spring to mix the lime and soil together. I am sorry that our "Sufferer" should have given such painful experience of it, but I hope he will give it another trial before he discards it altogether, as I have never found it fail as a fertiliser and as a destroyer of vermin.—T. LOWE, *Penketh*.

3976.—Building a Greenhouse.—The cost approximately of a house such as "C. C." intends building would be as follows:

	£	s.	d.
Bricks, hauling, and mortar	1	10	0
Wall plates, 44 ft., say 10 in. by 2 in., at 5d. per foot run	0	18	4
Ten uprights, 1 ft. 4 in. each, 3 in. by 3 in., at 2d. per foot run	0	2	3
Ten rafters, 5 ft. each, 3 in. by 1½ in., at 1½d. per foot run	0	6	3
Ridge, 15 ft., 3 in. by 1½ in., at 1½d. per foot run	0	1	10½
Sides, each 15 ft., 3 in. by 1½ in. 30 ft., at 1½d. per foot run	0	3	9
Two door posts, 7 ft. each, 3 in. by 3 in., at 2½d. per foot run	0	2	1
Two cross bars, 9 ft. each, 3 in. by 1½ in., at 1½d. per foot run	0	2	3
Twenty-four sash bars, 5 ft. each, 3 in. by 1 in., at ½d. per foot run	0	5	0
Glass, say 206 sq. ft., 15 oz., at 2d. per square foot	1	14	4
Putty, say 30 lb. at 1d. per lb.	0	2	6
Paint, two coats, 15 lb. at 4½d. per lb.	0	5	7½
Door	0	10	0
Total	6	5	1

"C. C." does not say whether he intends having wood stages or brick pits. If the latter, he will have to add to the cost of the bricks for the sides and pathway. If he is well situated for obtaining these, he may possibly lessen the cost materially in this item, as I had to pay considerably for the hauling. I bought my wood somewhat cheaper than I have stated here, and so perhaps may "C. C." It can be bought at the yard planed and sawn by machinery of the particular thicknesses indicated, and I would advise him to buy it this way and cut it to the lengths wanted. Sawing and planing by hand take up a great deal of time, which might be more advantageously employed, and seldom looks so well. To strengthen my house I got a smith to make some angle pieces of iron, 1 in. by ⅛ in., which I screwed to the rafters and uprights at the eaves, and also cross pieces 1 ft. long to brace the rafters together at the apex of the roof. These can be had, by ordering from a smith, at 6d. each, and tend to give greater strength. The corners I mortised and braced with angle irons. The door being a very troublesome part to make, "C. C." may be able to buy an old one, as I did, and, and by taking out the top panels, have a very respectable looking article at very little cost. The spaces between the sash bars sometimes vary a little in width, and he will find it best to buy the glass and glaze one sash at a time, unless great care is taken to keep the various widths distinct. The eighth of an inch makes a great difference in regard to the firmness of the glazing, as I found by experience. It would be better to glaze with as few laps as possible, and I would advise, merely for the sake of handiness, to have two lengths of glass in the roof only, which would make one lap each bar, because, even with the greatest care, it is difficult to get them air tight, and being for Cucumbers, where all the heat ought to be conserved, this is the more necessary. The sides, being only 16 in., of course can easily be put in without having a lap. The upper panes on the roof will require support with tacks, until the putty gets sufficiently hard, and the rabbeting ought to be done by the plane, and not pieces nailed on, as the width of the bars, 1 in., is sufficient to allow this, besides admitting more light, which is of the greatest importance.—G. S. C.

3922 & 3931.—Gravel for Walks.—I have been in the same difficulty as you are. I have used asphalte for some walks, black cinders for others, and red cinders for others. Asphalte makes a clean, dry walk, and when properly laid and mixed with gravel it is lasting, but not very sightly. All kinds of cinders, broken sandstone, broken bricks, or burnt clay are sloppy and pasty in wet weather, and lifts in the frost. If near London I cannot think of anything so good as the finer flint gravel, which will set well and gives a charming colour against grass. There are gravel beds which produce another kind similar in colour, but angular; this also sets well. In my difficulty I got a small cargo from Jersey, which can be delivered in any place near a seaport for say 12s. to 15s. a ton, and this is beautiful it will set for a carriage drive and become as hard as asphalte, while the rich brown colour contrasts well with the lawn. My impression is this is equal to anything, and better than most things which can be obtained. I expect that it could be obtained cheaper than this near London, where it is used for park drives, &c.—G.

3961.—Scale on Vines.—I am strongly against the practice of using paraffin on Vines, as a few years ago I saw the evil effects of using it. It was used with Gishurst. If you have used Gishurst alone and have found it has failed, try the Soluble Fir Tree Oil Insecticide, sold by all seedsmen, but care must be taken in mixing it—about ½ pint of oil to 6 quarts of lukewarm soft water. Apply this to the Vines with a paint-brush, and you will have little trouble in the future. Take care never to allow any plants to remain in the house affected with scale.—T. LOWE, *Penketh*.

3971.—Melons and Figs.—I would not attempt to grow Melons in such a structure, as they require more heat than would suit the other plants. But you might try a few plants of Melon Munro's Little Heath in 12-in. pots, trained to a flat or conical-shaped trellis. Figs would answer well on the end or back wall of a greenhouse, but not on the top of the house. They require assistance during the growing season in the shape of manure water, and occasional stopping of the shoots to induce them to form their fruit more perfectly.—THOS. LOWE, *Penketh*.

3831.—Holly for Walking-sticks.—Cut any time during winter, and after removing the bark put them to dry gradually. When dry round off the knots with a knife, and rub down smooth with sand-paper. To stain a dark yellow, rub them over with nitric acid, and hold to the fire. Lighter shades may be given by diluting the acid more or less with water. To stain them black, treat in the same way with sulphuric acid. Polish by repeated rubbings

with linseed oil, or give two coats of varnish, and when dry polish with powdered pumice-stone and afterwards with whitening. — J. MARTIN.

4006.—**Lilies in Towns.**—The following kinds, or any of them, would be suitable for growing in towns Lilium Browni, candidum, croceum (the Orange Lily), chalcedonicum, elegans, speciosum album, s. rubrum, s. roseum, the Tiger Lily, and well-known auratum. The above will make a good collection, and one worthy of cultivation, and any one of them will make good strong plants and thrive in a town, planted in good, rich soil, about 9 in. deep.—THOS. LOWE, *Penketh*

4007.—**Pond Leaking.**—First well damp and ram the bottom; then place evenly over it 6 in. of quicklime, then 6 in. of clay, to be well puddled and tightly rammed. Upon this rough stones or gravel may be placed. Without the lime worms work through.—W. H.

3952.—**Garden on Unused Well.**—Finding no one else has done so, I earnestly request "E F." to cover his unused well with a stone slab. I heard recently of a fatal accident caused by the boards on the top of an unsuspected well under garden soil giving way.—A COUNTRY DRUGGIST.

4027.—**Cyclamen Leaves Shrivelled.**—*Ferndale.*—The leaf appears to have dried up from want of water. Cyclamens in windows want plenty of air and very strict attention to watering, cleansing, &c.; indeed, unless under very favourable circumstances, Cyclamens are not suitable plants for windows.

4028.—*T. Jones.*—Brown's "Forester" is the most likely book to suit you, but it is expensive, viz, 31s. 6d. Most works on gardening may be had at our office.

4029.—**Charcoal.**—Is animal, vegetable, or mineral charcoal best for gardening purposes?— DUNEDIN. [Vegetable.]

4030.—*Subscriber, Guernsey.*—If you will send us flowers and leaves of the plant you wish to know the name of we will give you all the information you require respecting it, but we cannot give advice on the culture of an unknown plant.

4031.—**Heating Greenhouses.**—I have three small greenhouses, altogether heated with 374 ft. of 3-in. pipes; the boiler is a conical one (No. 1 C). I find it most extravagant, in seven days burning five sacks of coke and two sacks of small coal, value 7s. 6d. Can you tell me of a more economical apparatus? and the cost of same?—O. C., *Wimbledon.* [The various forms of saddle boilers are, generally speaking, more economical than the upright ones, inasmuch as if properly set they will burn up all ashes and other inferior kinds of fuel. Much, however, may be saved with your present boiler by judicious stoking. In the first place the coke should be reduced to pieces about the size of hen's eggs, and kept well wetted. In the second place, when you have a good fire established and a good heat in the pipes leave only enough draught under the furnace to insure a steady combustion. A fire thus treated will last for many hours without attention, and will retain a good heat in the pipes. We would advise you to try your hand at economical stoking before changing your boiler. But, after all, we do not think that the length of piping you have can be efficiently heated in winter with very much under 7s. 6d. per week.]

4032.—**Soil Shrinking from the Pots.**—In my greenhouse, which is heated by a flue, there is a tendency for the mould in the pots (of all sizes) to shrink away from the sides of the pots, and consequently when they are watered the water runs rapidly away between the earth and side of the pot. Can you assist me to prevent this, and suggest what is the cause?—C. C. [You potted the plants in new pots without soaking them. All new pots should be soaked in water at least six hours before being used. Those plants you have in pots now may be soaked in a bucket of water for half-an-hour each time they become dry till the pots get well soaked.]

4033.—**Index to Gardening.**—*Query.*—A complete index to the second volume will be issued at the end of February, when the volume is completed. Index to Vol. I. may be had from the office, by post 1½d., or through newsagents 1d. each.

4034.—**Removing Old Asparagus Roots.**—Some land forming part of a garden, being likely to be required in the course of next summer for building purposes, will you kindly inform me whether it would be worth while to remove all or any of the plants from some Asparagus beds in good bearing which were planted about ten years ago? and if so, when would be the best time for, and what would be the best way of carrying out the job?—RUS IN URBE. [We would lift the plants with a fork and place them at once in a frame on a bed of leaves and manure, and get a crop from them in March; afterwards throw them away. They are not worth planting again.]

4035.—**Cutting down Pentstemons.**—I have several Penstemons in my garden which are now as fresh and green as they were in July. Should they be left as they are or cut down?—J. S. M.; [Leave them till March, and then cut them down.]

4036.—**Salt as a Fertiliser.**—I think there must be a mistake with the figures in answer to the above query (3925); it says 6 cwt. of salt per acre is about 1 lb. per rod; the way I have reckoned it I find it is 4 and one-fifth lb. per rod.—T. BOX. [T. Box is quite right in his correction; the words should have been "about 4 lb to the rod;" the mistake was quite inadvertent.—A. D.]

4037.—**Turfy Loam.**—Does turfy loam mean sods cut from a lawn or grass plot in which the Grass has died? and what is the quickest way of killing the grass in sods, so as to make it useful for the garden?—R. H. D. [The quickest way to prepare turfy loam is to cut the sods in autumn and build them grass-side downwards in a large square heap. By the following spring the heap may be chopped down and the soil used, or if left for another year it will be none the worse.]

4038.—**Tobacco Smoke and Ferns.**—*Young Beginner.*—Fumigating Ferns with Tobacco smoke requires great care, as the fronds soon scorch. It should be done lightly for several nights in succession.

4039.—**Sulphur and Mushrooms.**—*Young Beginner.*—The fumes of sulphur would certainly not improve a crop of Mushrooms. With what aim do you apply the sulphur?

4040.—**Strawberry Plants for Forcing.**—*Young Beginner.*—Put them in the greenhouse at once on a shelf near the glass.

4041.—**Maiden-hair Ferns in Rooms.**—Will you tell me how to keep Maiden-hair Fern in a sitting-room? I have tried it several times and the fronds wither away; it has always been taken out of a stove house.—SUBSCRIBER. [Grow them in a cooler temperature, and do not put them in the room till the fronds are full grown. If gas is burnt in the room it is fatal to Ferns.]

4042.—**Hyacinths in Glasses.**—*Hyssop.*—The water should be renewed sometimes. A few bits of charcoal will keep it sweet for some time.

4043.—**Syringing with Soot Water.**—Will it injure plants to syringe them with water in which soot has been soaked to make manure water? it is perfectly clear.—INQUIRER. [It will make the foliage dirty and do no good. Use clean soft water.]

4044.—**Pruning Yew Hedge.**—I have a Yew hedge which has grown out at the top, but is thin and bare below. If I cut it thoroughly in at the top, will it put out and grow thick below?—HYSSOP. [Yes; or if you could bend down the shoots to the bottom it would answer the same purpose. Do it in March or April.]

4045.—**Planting Old Onions.**—Will some Onions left growing from a crop planted last spring grow to any size if planted out this spring like August sown ones for extra large size?—R. H. D. [No; they will run to seed directly.]

4046.—**Cropping after Celery.**—Which will be the best crop to plant on ground from which Celery has just been dug—Beet or Parsnips?—R. H. D. [Either of these crops will do equally well. Peas will also do well on such land.]

4047.—**Potting Ferns.**—When will be the best time to pot seedling Ferns at present growing on the walls of the greenhouse? and when should Ferns be repotted?—R. H. D. [In March or April.]

4048.—**Petunia Cuttings.**—*F. Wood.*—Unless you have a bottom-heat bed you had better wait till spring. The plants will flower in early summer if well grown.

4049.—**Christmas Roses.**—*A. B.*—Plants of the large-flowered Christmas Rose were advertised in our columns in autumn. They may be had from most good nurseries.

4050.—**Paint on Greenhouse Glass.**—*Greenhouse.*—We presume the glass was painted in summer to afford shade, a most unwise proceeding. A little whitening and milk would have answered the purpose better, and could have been easily removed. You must get all the paint off your glass to admit light to the plants if you wish them to thrive.

4051.—**Origin of Rhubarb.**—Can you inform me what class and family the Rhubarb belongs to? Is it a fruit or vegetable? and where did it originate?—T. W. [Rheum rhapodicum is the botanical name of the Rhubarb used for culinary purposes. It belongs to the genus Polygonaceæ. It is a native of Central Asia, and has been grown in this country since the fifteenth century. The leaves of Rhubarb were formerly used as a substitute for Spinach, to which they were considered superior. Mr. Myatt, of Deptford, was the first to bring Rhubarb as it is now used into prominence in the market, and it is now grown by the acre in most market gardens. It is a vegetable.]

4052.—**Planting Anemones, &c.**—How should I manage as regards aspect, time of planting out, and distance apart, with some seedling plants of Anemones, Geums, and Lychnis chalcedonica? Also, may I count upon their flowering next summer? The seed was sown last July.—AMATEUR. [They should have been planted in autumn, but may be planted now if the weather is open. The Anemones will probably not flower till next year; the others may.]

4053.—**Fixing Hot-water Pipes.**—*Circulation.*—The greater fall you can get the better the circulation. A fall of 4 in. in 40 ft. would do, provided the top of the boiler was 1 ft. or more lower than the pipes where they enter the house. We should have a greater fall than this if possible.

4054.—**Transplanting Hollies.**—*R. G. M.*—April will be the best time.

4055.—**Propagating Variegated Hollies.**—*R. G. M.*—These do not strike freely from cuttings. They are usually grafted on stocks of the common kinds.

4056.—**Grafting Plums.**—Can a Plum be grafted on Bullace trees with success? [Yes, if properly done.]

4057.—**Double Convolvulus.**—*E.*—From any good nursery or seed house.

Names of Plants.—*Ignoramus.*—The Winter Heliotrope (Tussilago fragrans).——*W.*—Abutilon vexillarium; plant it out in sandy soil in a greenhouse, or grow it in pots in the form of standards.——*Dorking.*—Polytrichum commune.——*J. L.*—1, too small to name; 3, Cassia sophora; 4, Euonymus europæus; 4, Stachys lanata.

QUERIES.

4058.—**Azaleas Dying.**—I have a lean-to conservatory which faces the east, and I get rather more sun than I want in summer, and even in winter I get an hour or two when there is any sunshine. It is heated by hot-water pipes, and the winter temperature may we set down as 44° to 50° when the sun shines in winter, and the temperature is easily run up to 65°. I give plenty of air on every opportunity. I grow very satisfactory Pelargoniums, Fuchsias, Cacti, Primula, and many kinds of Fern. But I can't grow Azaleas, and I want to know why. I buy nice plants set with flower-buds. They flower; then when done in spring I put them out in a shady place after a little time. I pot them into one size larger pot, using peat and sand. In October they come indoors, and look beautifully set with buds, and so they remain till spring, and I seldom get a bloom. In some years they do give me a few flowers, and then the leaves all turn yellow, drop off, and the plant dies. I never yet had one which lived more than two years. A hint on this point will be taken as a great favour. The success I have with other things leads me to hope that I may yet grow an Azalea. Again, I can't get Cyclamens to flower; I suppose my place is not hot enough; if it were hotter, however, it would start my fancy and large-flowered Pelargoniums, and ruin them.—PERPLEXITY, *Streatham.*

4059.—**Liquid Manure.**—I shall be much obliged to any one who will advise a lady as to the best and most convenient kind of liquid manure to use in her greenhouse and flower garden.—T.

4060.—**Ampelopsis Veitchi.**—I have two plants of this, one in a cool greenhouse, the other out-of-doors. The one in the greenhouse clings pertinaciously to the wall, and cannot be detached without breaking, except by the aid of a thin-bladed knife. The out-door one does not cling at all, but has to be nailed while growing. Why this difference?—M. L. B.

4061.—**Fruit Trees on Clayey Soil.**—I have a wall in my garden, Tottenham, about 16 ft. high and about 60 ft. long, and wish to train thereon two Pear trees, one Plum tree, and a Grape Vine. I also wish to plant some Raspberry canes. What are the best varieties and the best fruit producers? When ought the trees to be planted? The soil is clayey.—H. J. W.

4062.—**How to Fix a Coil Boiler to a Slow Combustion Stove.**—I have the stove named in my greenhouse, and if it is possible I wish to fix a boiler with pipes; if it is possible, would any one be so kind as to give me the necessary instructions.—W. G. C.

4063.—**Berried Iris.**—I have had some berries given me which are said to be berries of the Gladwin Iris. Will any one kindly inform me whether I can raise plants from them? I have no greenhouse, but have frames in which they could be raised in heat. What treatment would the berries and the plants, if raised, require?—GEM.

4064.—**Cutting Back Vines.**—I have just taken to a greenhouse in which are four Vines; my predecessor dressed them with a solution of soft soap, soot, sulphur, and paraffin oil, and the Vines, which were about six years old, were killed down to the holes of the brickwork. They have shot out from the brickwork strong rods about 14 ft. long; two of the Vines have made three such rods, one of them two rods, two others four each, and one made six. Should these be left, or how many should be cut off, and how far the rest cut back? I want as many Grapes as I can get. Is 50° too high a night temperature? My house is heated by a brick flue. If there are too many rods to be left, can I strike them in pots?—J. FREER, *Kettering.*

4065.—**Grafting Old Fruit Trees.**—I shall be glad if some one will give me a few practical hints on this subject.—J. T.

4066.—**Mounting Ferns.**—I am desirous of forming a herbarium of Fern fronds, and should be glad to know what is the best kind of paper for the book, and the best way of fastening the fronds in it. I believe there is a special kind of paper which preserves the colour pretty well usually used for this kind of thing, and should be glad to know where I can get it.—E. T. B.

4067.—**Liliastrum (Anthericum).**—I have been much puzzled as to how this grand old hardy herbaceous plant gets its name, my botanical work (Grindon) describing it "with star-like flowers." Failing to find any such similarity in the handsome snow-white flowers, I had lately occasion to take some plants out of the ground, and to my surprise I found each separate root as star-like in shape as the starfish so commonly to be found on our seashores. Can any of your readers enlighten me as to the derivation of the name, if it does not come from the shape of the root? I may add that this plant grown under glass (not forced) is an admirable addition to the conservatory, and worth any care and cultivation there or in the garden.—FLORENCE.

4068.—**Vines in Cool House.**—Perhaps some one will give me information on the following question: About two years ago I planted a Gros Colmar Vine in a cool Vinery, and although it has borne several bunches this year, they have not ripened well, nor have they grown out well, and I am told that the Vine ought to have been planted in a hot Vinery. What I want to know is, whether it would answer to graft a Black Hamburgh on to the Gros Colmar stock, and the Gros Colmar on to a Black Hamburgh stock in my forcing house. My object, of course, is to save time.—G. M.

4069.—**Warming and Ventilating.**—Will some one give their experience as to the best and most economical means of heating and ventilating greenhouses where smoke is objected to? Hot water heated by gas is said to be a failure, besides being very expensive; and oil stoves do not give the pleasant atmosphere which one feels when the house is heated by hot-water pipes.—G. S. C.

4070.—**Worms in Pots.**—Can any reader of GARDENING tell me how to get these out of a pot containing a Tree Fern? I want to fresh pot the plant, but should like to get rid of the worms first, as the plant is too large to have all the mould shaken away. It is in a No. 1 pot.—H. R., *Walton.*

4071.—**Iris anglica.**—I have a few bulbs of this. I should like to know if they are quite hardy; if they should be taken up every year; if I should plant them now or wait till spring.—J. S.

4072.—**Cineraria Leaves Curling.**—Will any reader tell me the cause of Cineraria leaves curling? mine are just showing bloom, and the leaves are all beginning to curl.—YOUNG BEGINNER.

4073.—**To Renovate Garden Paths.**—Will some one inform me the best method of making a good path for kitchen garden by mixing coal ashes with the gravle

already laid down? and also if this will prevent Dandelions and other obnoxious weeds from growing in the walks?—C. M. F.

4074.—**Garden on the Clay.**—I have a small garden which is on the clay, and after I get 1 ft. below the surface the clay is very close. I have been thinking that if I dug in some coal ashes sifted fine, and also a little lime rubbish, it would much improve it, and also to mix coal ashes, lime rubbish, and the earth from worm casts, of which there is plenty Would it make a good compost for striking cuttings in, and for seeds in pots, of course taking care to have plenty of drainage material at the bottom of the pot? A few of my plants and shrubs seem to thrive, but many others seem to make but little progress.—G. R.

4075.—**Pruning Clematis.**—I have a young Clematis, C. Lawsoniana. It grew about 10 ft. high the last season, but the frost came before the bloom opened and cut it down to 4 ft.; what is the proper way to prune t?—LEEK.

4076.—**Tropæoum speciosum**—Where can I procure tubers or seed of Tropæolum speciosum? I have seen a gentleman's lodge covered with it in a colder climate than this. If I procure them, how am I to treat them for growing out-of-doors?—LEEK.

4077.—**Heating by Steam.**—I have a small greentouse, 12 ft. by 9 ft., which I have tried without success to heat with paraffin stoves. I could have steam brought from a large mill boiler, but the distance for it to travel will be 200 yds. What sized pipes should be in the greenhouse? and how many times should they be placed round it? also what distance ought they to be from the shelves? I should like the temperature to keep at 45° in the frosty weather.—SILVER STORK.

4078.—**Fruit Trees for Monmouthshire.**—Will any reader tell me what Apples, Pears, and Cherry trees are likely to do well in the neighbourhood of Trelleck, Monmouthshire, which is about 600 ft. about sea level? Will Vines, Raspberries, and Strawberries succeed there?—DEVAUDON.

4079.—**Hoof Parings.**—Are parings of horse-hoofs (to be obtained at a farrier's) any good for manuring Grape Vines? if so, what quantity for each Vine?—H.E.M.

4080.—**Treatment of Muscat of Alexandria to bear Late Grapes.**—I have a Vinery containing six plants of the above Grapes; my object is to have them fit for market in November and December. This year the Grapes were small, and began to shrivel about November; they mostly looked green instead of golden. The Vines are about to be pruned and dressed. There is long litter on the outside border at present; about March I propose making up the border with ½-in. bones and rotten manure. The roots are outside. The house is heated with a brick flue. Aspect south, but in a cold, low situation in North Yorkshire. The border seems well drained. At present there are cuttings in the house to benefit by the fire we keep in cold and damp weather. Will they do the Vines any harm?—SCRUTON.

AQUARIA.

MY FOUNTAIN.

A CORRESPONDENT has recently, in No. 90, narrated how he made a miniature fountain suitable for an aquarium or Fern case. His method is very feasible, but perhaps it will not be superfluous if I also inform your readers as to the construction of a larger fountain in an equally simple manner.

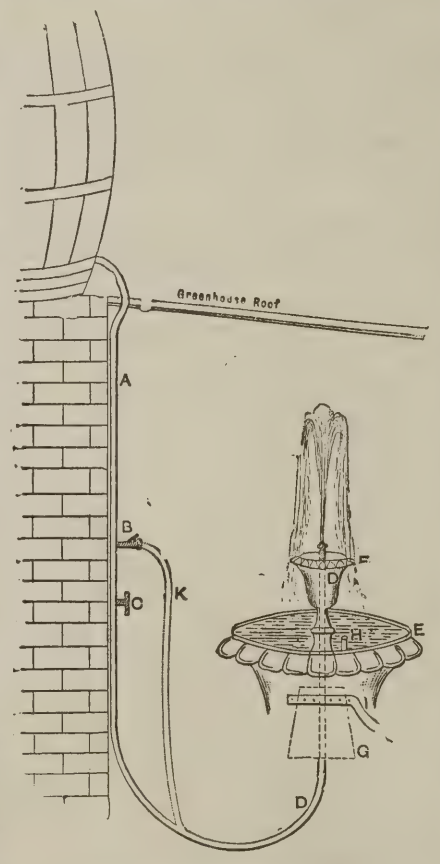
Outside the house I have a large butt supplied from the main, and containing about 200 gallons of water, which is devoted to garden purposes. In the garden below there is a lean-to greenhouse with rockwork running round two sides. In the corner on this rockwork is my fountain. If the annexed drawing be examined, the reader will see the position of the fountain in relation to the supply. A is a 1-in. leaden pipe descending to the tap B, where the garden hose is attached when required. D is a piece of leaden pipe through the basin. This may be connected with B by india-rubber tubing, as at K, so as to take off and on in the same manner as the hose, or may be bodily joined to A beneath the tap. There is no difference in either with regard to the force of water, but the latter will not leak and is more sightly. In this case, however, a second tap C will be required.

Having got thus far, a basin was wanted. This was found in an old garden vase or urn E of the ordinary pattern, but with the foot broken off. It measured about 18 in. across, inside measure, and had a hole in the bottom. I placed it in the desired position, about 9 ft. 6 in. below the butt, and in the centre put a flower-pot G to serve as a stand for another vase F about 8 in. across. Through all this the pipe was carried and a small jet screwed on to the top. Then the basin having been levelled, and all holes, &c., stopped with Portland cement, the water was turned on and falling into F gradually overflowed and filled E below.

So far the fountain is complete. But the overflow must be considered, as if the surplus water runs over the edge on to the earth around, it tends to make it sour. Therefore, before the cement is used provide a leaden pipe for the waste (not too small, or it will get choked), carry it through the bottom of the basin, the end H being just below the level of the water, and bring it up again outside, as at I at a still lower level. Pierce the last 6 in. with holes and bend it horizontally, the end being stopped.

Below this I made a little watercourse with burrs down the face of the rockwork, and the water running down fell into a hollow in the ground coated with cement, whence it escaped into the garden.

People have so frequently a separate supply of water for garden purposes, that the chief requisite is at once provided, but where this is not present a fifty or sixty gallon tank can be elevated about 10 ft., and will be amply sufficient for a corner in a small garden. All that follows is easy and can be done by oneself. Of course a little money must be expended, but



Fountain for Greenhouse or Aquarium.

some ingenuity and adaptability to circumstances will effect wonders.

As it is, I have a pretty little corner in my greenhouse with Ferns round the fountain, and a jet which will rise to 10 ft. or 12 ft. in the air, with gold fish in the water, and with the overflow trickling down a little waterfall, which is spanned by a miniature bridge about 1 ft. in length. Add to all this that I have moreover the gratification of having done it myself, from the basin to the bridge. "Go thou and do likewise." JET D'EAU.

BEES.

Feeding Bees.—The last week in July I had two hives showing symptoms to swarm. I placed a nadir under each of them. In September I drove the bees from the top hive into the nadir of hive No. 1, and in a few days after I did the same with No. 2, but to my surprise I found the bees had not built any comb in the nadir; so I examined No. 1, and found the bees had only just began to build, so I united them and set to work to feed them. I gave them 12 lb. of best lump sugar made into syrup, and I also gave them a lot of comb to clean. In the last week in October I covered them down for the winter. But they are at work nearly every day, almost as numerous as a fair strong hive in summer. Is it for want that they are out so? and must I feed?—D. R.

WATER PLANTS IN GLASSHOUSES.

AN expensive structure for growing the Victoria Lily cannot be erected in every garden, but everyone who possesses a plant-stove, greenhouse, or conservatory, may, with but little trouble or cost, devote some portion of it to the cultivation of the more beautiful water plants. The introduction of a slate tank into the plant-stove occasions but little extra trouble and expense, while it may be made one of the most interesting features in the house; or one side of the side-benches might be covered with several of these shallow tanks placed side by side. Their size will vary according to the width of the staging, but from 3 ft. to 4 ft. square, and 1 ft. or 15 in. deep, will, in most cases, be amply sufficient. These portable tanks are in many cases preferable to permanent erections, as, during the winter months, they can be removed and stored away in any dry shed until required for the next season, or the water they contain may be emptied out and plants in pots can then be set inside in the usual way. In tanks like those above described, a great variety of aquatics can be grown that will not be less interesting than more common plants. Among the commoner aquatic plants there are some which should be in every garden, as the Aponogetons, their forked sprays of silvery bracts being most valuable for cutting. Vallisneria spiralis is always interesting as a microscopic object, and some of the smaller tropical Water Lilies grown in tanks like those above described unfold their pure white, bright rose, or cœrulean-blue flowers as freely as those of our native ponds and streams. A little good sandy loam is the best compost in which to plant the stronger-growing kinds, while some of the smaller Pistias and Pontederias will float on the surface. These tanks are valuable for assisting the growth of other plants as well as aquatics; for example, Palms grow far more vigorously during the hot summer months if the bases of their pots are sunk about 2 in. into the water. Callas grow far more robustly and flower better if the pots are plunged overhead in the water, and if they are sunk deep enough, say, from 2 ft. to 3 ft., the plant will withstand our climate all the year round. Aponogeton distachyon may either be set in a dwelling-room window, planted in a little earth at the bottom of an inverted bell-glass, or it will grow vigorously in a shallow tank in the open air, where it seldom fails to flower freely throughout the spring and summer months.

WATER PLANTS IN STOVES AND GREENHOUSES

A. monostachyon bears pretty pink blossoms on its undivided spikes. It is smaller in habit than the last, but requires the warm humid temperature of the stove aquarium. Umbrella Sedge of Madagascar (Cyperus alternifolius), grown in a pot in ordinary compost, makes pretty little plants 1 ft. to 2 ft. high, and well adapted for ordinary decorative purposes; but, if planted in a pot of rich soil and partly plunged in the tank, it often produces large growths 5 ft. or 6 ft. in height. There is also a pretty variegated form very valuable for decorative purposes, although it is apt to revert to its normal green state. If the plant is grown in very poor soil, with at least one-half of sand, it comes beautifully coloured, each leaf being striped with pure white. This plant is always useful, especially for table decoration and for grouping along with choice flowers in the drawing-room vases. Its foliage radiates in a gracefully drooping manner from the apex of the slender stems, and is distinct from any other decorative plant. Limnocharis Humboldti bears beautiful, clear, soft yellow flowers among its floating foliage. The general port of the plant is similar to that of Aponogeton distachyon, but its leaves are heart-shaped, and the plant is sufficiently hardy to stand out-of-doors in sheltered tanks during the hottest portion of the year only. Nymphæa cœrulea is a plant, with bright green foliage and light blue flowers, both of which float gracefully on the surface of the water. N. pygmæa is a charming companion to it, and might be grown in an inverted bell-glass. It has heart-shaped leaves and pearly-white flowers. Nelumbium speciosum, the well-known "Sacred Bean" of Egypt, is best treated as a sub-aquatic, or it can be grown in a tub half filled with good sandy loam, covered with about 12 in. of water, so as to keep the roots in a consistent state of moisture. It is easily propagated from seeds sown directly after Christmas. Common Water Lettuce (Pistia stratiotes) is of a light and fresh green colour, and forms a most interesting object in the aquarium. This plant readily propagates itself by offsets. Pontederia crassipes is a most curious plant, having inflated leaf-stalks to its kidney-shaped leaves, and which give it the general appearance of a Sarracenia. It should be grown in every stove tank as a most interesting and curious object. Vallisneria spiralis is a Grass-like plant, which roots freely into the mud at the bottom of the tank, and sends up its female flowers on long, spiral, hair-like stalks, often 15 in. to upwards of 2 ft. in length.

THE BEST ROSES GROWN.—Hybrid Perpetuals, Moss, Climbers, and Austrian (best exhibition sorts); dwarfs, 10s. per dozen, 50s. per 100. Send for list of 300 sorts to choose from.—W. FARREN, How House Nurseries, Cambridge.

CHEAP PLANTS.—Pelargoniums, well-rooted, 2s. per doz.; Spiræa, 3s. per doz.; choice Tea-scented Rose trees, 10s. per doz.; Violets, any variety, 1s. per doz. roots; Rose cuttings from 200 choice varieties, 6d. per doz.; ditto Fuchsia, 6d. per doz.; ditto Coleus, 9d. per doz.—T. HAWKINS, Haven Green, Nurseries, Ealing.

CHRYSANTHEMUMS! CHRYSANTHEMUMS!!—Strong-rooted cuttings from 200 of the large-flowering exhibition varieties, 1s. 6d. per doz., or 15s. the collection.—T. HAWKINS, Haven Green Nurseries, Ealing.

SEEDS! SEEDS!!—True Telegraph Cucumber, Marquis of Lorne, Black Spine, or Tender and True, 20 seeds for 6d.; Hardinger Wallflower, 7d. per oz.; Cyclamen, large flowering varieties, 6d. and 1s. per packet; Sweet Peas, white or red, 6d. per packet.—T. HAWKINS, Haven Green, Nurseries, Ealing.

EAST LOTHIAN INTERMEDIATE STOCKS—the finest Stocks grown; bloom from July till November; splendid for exhibition. Todd's superb crimson, scarlet, purple, and white, 6d. per packet, 3 packets for 1s.—TODD & CO., Seedsmen, Maitland Street, Edinburgh.

NEW PEAS.—Amateurs' Trial Packets, 6d. each, post free 7d. Culverwell's Giant Marrow, Day's Sunrise (first early), John Bull, Invincible (sharpe), Minimum, Pride of the Market, Carters' Stratagem, Telegraph, and Telephone.—TODD & CO., Seedsmen, Maitland Street, Edinburgh.

ANEMONE JAPONICA ALBA.—Strong Plants of this beautiful Hardy Autumn-flowering Anemone (see GARDENING ILLUSTRATED, September 4, 1880), 1s. each, post free.—GEORGE PHIPPEN, Victoria Nursery, Oxford Road, Reading. Established 1862.

LILIUM AURATUM.—Golden-rayed Lily of Japan; magnificent blooming bulbs, fresh imported with clay protection, sent carefully packed and carriage paid, 9s., 12s., and 18s. per dozen.—M. VEREY, 27, St. George's Road, Regent's Park, London.

EWING & CO., The Nurseries, Eaton, near Norwich.—ORNAMENTAL TREES and SHRUBS (deciduous, flowering, variegated, evergreen, and coniferous); Climbing and Creeping Plants, Forest Trees, Fencing Plants, Fruit Trees and Bushes, &c. N.B.—New Roses for 1881, to be ready in March.

20,000 AQUILEGIAS (Columbines).—Mixed seedlings from seed beds of the best varieties, to flower next spring (sure to produce fine novelties), 1s. per dozen, 5s. per 100, 20s. per 1000, free.—W. FARREN, How House Nurseries, Cambridge.

LILY OF THE VALLEY.—Finest imported crowns of the true large-flowering variety; produces long spikes of beautiful large bells; splendid for forcing or pot culture. 1s. 3d. per doz.; post free.—TODD & CO., Seedsmen, Maitland St., Edinburgh.

CHOICE CHRYSANTHEMUMS.—Mr. DAVIS can supply Cuttings same as last season, from his splendid Collection of 400 Exhibition varieties, at 8s. per 100; single dozen, 1s. 4d., post free. Correctly named. Descriptive List free.—60, Warner Road, Camberwell, London.

LAING'S GOLD MEDAL BEGONIAS.—Choice Hybridised SEED, superior to all others, is harvested from their unrivalled collection, which was again awarded first prizes at all the London great flower shows. Sealed packets, by post, 1s. and 2s. 6d. each. All first quality. The Trade supplied.—JOHN LAING & Co., Seedsmen, Forest Hill, S.E.

AMATEURS.—Cuttings.—Twelve of the best Incurved Chrysanthemums extant for 1s. 6d., including Empress of India, G. Glenny, Blonde Beauty, Barbara, Virgin Queen, Pink Perfection, Mrs. Dixon, G. G. Glenny, Faust, Baron Beust, Mrs. G. Rundle, and Prince of Wales; twenty-four varieties, 2s. 6d.—J. JAMES, New Road, London Road, Leicester.

CUCUMBER SEEDS.—Wells's Improved, a cross between Telegraph and Bluegown; strong grower and abundant cropper; length, 18 in. to 20 in. Splendid Market Cucumber; per packet of seven seeds, 1s., twenty seeds, 2s. 6d. Seed Catalogue free.—W. WELLS, Earlswood Nurseries, Redhill, Surrey.

CUTTINGS! CUTTINGS!! CUTTINGS!!!—Pompone Chrysanthemums, six best varieties, Geraniums Vesuvius, Madame Thibaut, Wonderful, Fancy Pelargoniums in varieties; all the above in strong cuttings, 1s. 6d. per dozen, 10s. per 100, post free for cash.—MEADS & BOYLES' Nursery, Devonshire Grove, Old Kent Road, London.

ABIES DOUGLASI, about 12 in. transplanted, 1s. 6d. dozen; 7s. 6d. per 100. Cupressus Lawsoniana, do., twice transplanted, 1s. 6d. dozen; 7s. 6d. per 100. Pinus rigida (Swamp Pine, timber first-class), one year seedlings, 4 in., 7s. 6d. per 1000. All fibrous-rooted cheaper by the 1000 or 10,000.—JAMES HATHERALL, Brooklands, Weybridge Station.

SUPERIOR SEEDS, Post Free.—Rollisson's Telegraph Cucumber, warranted true, 12 seeds for 1s. Primula sinensis, white and red, a splendid strain, 1s. per packet. Tuberous Begonias, saved from the best English and Continental varieties, 1s. per packet. Trade supplied.—A. C. ROFFEY, Seed Grower, &c., Church Road, Croydon.

12 CHOICE CONIFERS, 1 to 2½ ft. high, well rooted, and furnished, 10s. 6d. 12 Choice Hollies, Golden, Silver, and Green-leaved, 1½ ft. to 2 ft., bushy and well-rooted, 18s. 12 Laurels, 1½ ft. to 2½ ft., bushy, of the best new and old sorts, 4s. 12 Choice Dwarf Roses, 7s. 6d. Broad-leaved Privet, bushy, 2 ft. to 3 ft., 9s. per 100; 3 ft. to 4 ft., 15s. per 100. List free.—J. J. MARRIOTT, Highfield Nurseries, Matlock.

SEEDLING BRIERS for budding next season, fine, 25 for 2s. 6d.; 50, 4s.; 100, 7s.; cheaper by the 1000. Also "The Villa Bundle of Small Fruits," very strong two-year-old fruiting trees, twelve each of Crown Bob and Whitesmith's Gooseberries, Victoria Red and Black Naples Currants, Fastolf Raspberries, and Keen's Seedling Strawberries, true to name, for 9s., or 2s. per dozen; cheaper by the 100 or 1000.—W. FARREN, How House Nurseries, Cambridge.

CHRYSANTHEMUMS! CHRYSANTHEMUMS!!—Strong stock plants to furnish cuttings, our selection from 300 of the best varieties grown, 4s. per doz., 25s. per 100. Strong cuttings of the best large-flowered Anemone or Pompone Chrysanthemums, 12 varieties, our selection, 1s. 6d., 50 varieties, 5s. 6d., 100 varieties, 10s., post free; cuttings of Japanese varieties, 2s. 6d. per doz.—W. CLIBRAN & SON, Oldfield Nursery, Altrincham.

CHRYSANTHEMUMS! CHRYSANTHEMUMS!!—J. WALLACE'S Prize Chrysanthemums, 500 varieties, 2s. per dozen, 12s. per 100; cuttings, 1s. 6d. per dozen; 8s. per 100. Paris Daisies (Marguerites), 12 fine plants, 3s.; six, 1s. 9d., post free. 12 new and beautiful Crotons, 9s. 12 new and beautiful Dracænas, 9s. 12 beautiful Ferns, 4s. 12 Gloxinias, finest strain, good bulbs, 4s. Package included. Cash with order.—Pellatt Road, East Dulwich, S.E.

ROSES and SPRING FLOWERS.—24 Strong dwarf Roses in 24 varieties, selected from the best H. P.'s (money could not buy better), and 100 strong spring bedding and border plants for 14s., half 7s. 6d. Daisy Snowdrift, the largest white Daisy extant, and a perpetual bloomer, has furnished hundreds of cut flowers this Christmas, 1s. per doz. post free; 10 splendid Pansies, named, 1s. 6d., post free; Pansy Blue King, 1s. per doz., and Viola Blue Bell, 1s. per doz., post free for stamps.—S. BURTON, Florist, Loughborough.

EVERGREEN HEDGES in great variety, very cheap. Descriptive price list on application.—RICHARD SMITH & CO., Nurserymen, Worcester.

THE most superb ROSES that money can buy.—Dwarfs, very strong and healthy, 12s. per dozen, 75s. per 100. Descriptive price list on application.—RICHARD SMITH & CO., Nurserymen, Worcester.

CLEMATIS for Bedding and Climbing Jackmani, strong plants, 12s. per dozen; other varieties, 15s., 18s., and 24s. per dozen. Descriptive list on application.—RICHARD SMITH & CO., Nurserymen, Worcester.

GLADIOLI.—TODD & CO.'S "WONDER" SELECTIONS.—For all classes of purchasers. Extraordinary value. No. 1 Wonder Dozen for 2s. 6d., free by post 3s.—Angele, Calypso, Ida, James Carter, Laura, Lord Byron, Napoleon III., Neptune, Penelope, Princess of Wales, Rebecca, and Romulus. No. 2 Wonder Dozen for 3s. 6d., free by post, 4s.—Achille, Comte de Morny, Colbert, Conde, Duc de Malakoff, Fulton, Lamarck, Lord Raglan, MacMahon, Marie, Thalia, and Vesta. No. 3 Wonder Dozen for 5s., free by post 5s. 3d.—Achille, Dona Maria, Eugène Scribe, Horace, James Veitch, Madame Furtado, Maria Dumortier, Meyerbeer, Mozart, Reine Victoria, Sir William Hooker, and Themis. No. 4 Wonder Dozen, 7s. 6d., free by post.—Amaranthe, Etaudard, Eugène Scribe, Hortense, Isabella, La Favourite, Lamarck, Meyerbeer, Phidias, Pericles, Sir Joseph Paxton, and Velleda. Gladiolus The Bride, one of the most beautiful of summer white flowers, invaluable for cutting, 2s. per dozen, post free.—TODD & CO., Seedsmen, 7, Maitland Street, Edinburgh.

Seventh Year of Distribution.

TELEGRAPH CUCUMBER (Warranted), 18 seeds, 1s.; 7 seeds, 6d., post free. The seed has been collected from handsome, well-grown fruit. Price per oz. on application.—R. W. BEEDELL, The Nurseries, Wallington, Surrey.

MAIDEN-HAIR FERNS, 4 for 1s., post free.—Testimonial.—"Mrs. Morris received the Maiden-hair Ferns this morning and was very pleased with them. She encloses 2s. in stamps for four to be sent to each of the enclosed addresses.—Heathfield, Mandy, Cardiff."—R. W. BEEDELL, The Nurseries, Wallington, Surrey.

PRACTICAL ECONOMY.

SEE our Handy Guide (designed for those who desire a grand display of the Newest and Best Flowers by a small outlay) sent free on receipt of a stamped directed newspaper wrapper.

NOVELTIES FOR 1881.

ANTIRRHINUM MAJUS NANUM PICTURATUM, Double White Eschscholtzia, New Mignonette "Golden Queen," Pyrethrum aureum selaginoides, Eschscholtzia carminea, New variegated-leaved Sunflower, New White Pansy "Snow Queen," New Tuberous Begonia "Begonia robusta perfecta rosea. Lobelia cardinalis, Salvia farinacea, the finest red and blue flowers in cultivation, each 6d. per packet.

THE best Strains of Asters, Stocks, Balsams, Carnations, Primulas, Calceolarias, Cinerarias. Tuberous Begonia Seed from the finest collections in Europe.

MILES' HYBRID SPIRAL MIGNONETTE.—A grand acquisition. Seed, 6d. per packet.

TUBEROUS BEGONIA SEED, in separate colours (crimson, red, scarlet, cerise, rose, magenta, bronze, buff, copper, orange), 1s. per packet, 5 packets for 4s. Primrose, yellow and white, 1s. 6d.; the 3 for 4s.; mixed seed, 1s. and 1s. 6d. per packet. Sow in January and February for a grand early summer display.

NICOTIANA LONGIFLORA, a deliciously fragrant plant with pure white flowers; one will scent a whole house; easily cultivated; almost a perpetual bloomer; seed, 7d. and 1s. per packet, with directions. Sow now.

CHRISTMAS ROSES, showing bloom specially grown for late flowering. Plant now to secure an abundance of white flowers next Christmas. Strong roots, 7d. each; six for 2s. 6d.; twelve for 4s. 6d.

GIBBS & COMPANY, Nurserymen, Deben Valley Nurseries, Woodbridge, Suffolk. P.O.O. with order. All carriage free.

BICKLEY'S PATENT HORIZONTAL SASH-BARS.—With these bars an amateur can easily make a greenhouse superior to any other plan.—For Descriptive Price List, &c., apply 7, Thorp Street, Birmingham.

J. C. STEVENS, HORTICULTURAL, SCIENTIFIC, and NATURAL HISTORY SALE ROOMS, 38, King Street, Covent Garden, London. Established 1760. Sales by Auction nearly every day. Catalogues on application or post free

LEAN-TO GREENHOUSES, 10 ft. long, by 8 ft. wide, £7 10s.; 12 ft. long by 5 ft. wide, £5 15s. Fitted with door, top and bottom ventilators, necessary fasteners spouts, 21-oz. glass, putty, painted one coat, and carriage paid to any station in England.—A. P. JOHNSON, Greenhouse Builder, Wilmington, Hull.

TO BE SOLD a few GOLD WATCHES, by the renowned McCABE, whose celebrated manufacture recently and finally ceased. Other eminent makers are also represented in the large Stock of Gold and Silver Watches at WALES & McCULLOCH'S, 22, Ludgate Hill, and 56, Cheapside, E.C.; all such instruments being warranted genuine, perfect in condition, and at about half ORIGINAL cost.

GARDEN Stakes, Labels, Virgin Cork, Mats, Raffia, &c. None cheaper.—WATSON & SCULL, 90, Lower Thames Street, London, E.C.

WANTED, by a respectable man, unmarried, a situation as gardener, single-handed; well experienced; good character.—Address, THE GARDENER, Beach House, Seaton, Devon.

GARDENING GUIDE BY HOOPER, finest work in our language for amateurs. Perfect in information fully illustrated. Price 2s. 6d., postage 5d.—HOOPER & CO. Covent Garden, London, and all booksellers.

COCOA-NUT FIBRE REFUSE, best quality.—1s. per 4-bushel bag, 30 bags 18s., 15 bags 10s. (bags included), truckload (250 bushels), free to rail, 21s.—Orders to A. FOULON, 32, St. Mary Axe.

TOBACCO CLOTH AND PAPER FOR FUMIGATING.—Buy of the maker direct. Cheapest and best in the market. Cloth, 8d. per lb., 28 lb., 18s. Paper, 7d. per lb., 28 lb., 16s. Best Roll, 9d. per lb.—J. DENYN, 73, Rendlesham Road, Clapton, London.

LEATHER HOSE (Second-Hand); 4000 feet for SALE. 1½ in. diameter, price 1s. per ft., in any quantity.—MERRYWEATHER & SONS, 63, Long Acre, London.

FIRE ENGINES and PORTABLE PUMPS (Second-Hand) for SALE very cheap; suitable for watering purposes or supplying reservoirs, tanks, &c., as well as for fire extinguishing.—Apply, MERRYWEATHER & SONS, 63, Long Acre, London.

THE NEW GARDEN HOSE.—Made upon the principle of the New Fire Hose used by Capt. Shaw, C.B., Chief Officer of the London Fire Brigade. There are twelve reasons why it is better than any rubber or fabric hose, and not the least important ones are—1st, it is much cheaper; 2nd, it is by far more durable.—MERRYWEATHER & SONS, Manufacturers, 63, Long Acre, London. Works—Greenwich. Private customers supplied at trade list prices; sample free.

New, Rare, and Choice Plants
EXTRAORDINARILY CHEAP.

J. H. LEY, having a large, healthy, and well-grown Stock of the following beautiful plants, will send them (carefully and perfectly packed) on receipt of P.O.O. No charge for packing, mats, or hamper if cash is sent in advance. *Half or quarter dozens at same rates.* Many plants are now offered at less than a quarter the prices of London firms, or of those who profess to be co-operative. See Catalogue! Inspection requested! Hundreds of Testimonials to the value of well and quickly-grown plants as compared with those kept in stock for years (the case in most nurseries) can be seen from the gardens of most of the Nobility and Gentlemen Amateurs in Great Britain.

		s.	d.
12	Adiantum cardiochlænum. This rare and most beautiful Maidenhair has been raised from spores for the first time; good plants	12	0
12	Adiantum farleyense, strong plants, single crowns; rapidly make specimens	12	0
12	Adiantum concinnum, a lovely Fern	6	0
12	Pteris tricolor, beautifully variegated	12	0

EVIDENCE OF QUALITY.

"The Primula seed sent last year, 1879, was very good in quantity and quality. I never had better. Send me another packet."—A. K. HUNT, Esq., Southerwood, Torquay, England.

"I have noticed seeds in your catalogue not seen in any list at this side of the channel, and enclose cheque for the things as marked. I am exceedingly fond of hardy perennials."—J. T. FORMAN, Esq., Bramcote, Nottingham, England, Feb. 24, 1880.

Wm. BAYLOR HARTLAND, Proprietor.

TOBACCO PAPER and TOBACCO ROPE for Fumigating.—For prices and samples apply to J. and E. KENNEDY, Tobacco Works, Amiens Street, Dublin.

RIMMEL'S AROMATIC OZONIZER, OR NATURAL AIR PURIFIER.—A fragrant powder producing, by simple slow evaporation in dwellings or places of public resort, the balmy, refreshing, and healthy emanations of the Pine and Eucalyptus forests. It is the most effective and only agreeable disinfectant. Price 1s.; by post for 15 stamps.—EUGENE RIMMEL, Perfumer, 96, Strand, 128, Regent Street; and 24, Cornhill, London.

GISHURST COMPOUND.—Used by many of the leading gardeners since 1859 against red spider, mildew, thrips, green fly, and other blight, in solutions of from 1 to 2 oz. to the gallon of soft water, and of from 4 to 16 oz. as a winter dressing for Vines and fruit trees. Has outlived many preparations intended to supersede it. Sold retail by seedsmen, in boxes 1s., 3s., and 10s. 6d.

GISHURSTINE preserves Gardeners' Boots, keeps feet dry, is perfect Dubbin. In boxes, 6d. and 1s. each. Wholesale by Price's Patent Candle Company (Limited).

AMERICAN BLIGHT on APPLE TREES CURED by rubbing a wet hard painter's brush on Gishurst Compound and working the lather into the infected part.

COCOA-NUT FIBRE REFUSE, by Chubb's Patent Process, as supplied to all the Royal Gardens and Principal Nurseries of Europe. Useful at all seasons. Invaluable for Potting, Plunging, Forcing, Ferneries, Strawberries, Bedding-out Plants &c. Destroys all Slugs and Insects. Sacks, 1s. each; 15 sacks, 12s.; 30 sacks, 20s. (all sacks included). Van-load at works, 4s.; ditto, delivered within five miles, 10s.; Truck-load (equal to about 300 bushels when dry), free on rail, 25s. Terms, strictly cash with order. To obtain the genuine article, buy direct from the Manufacturers, CHUBB, ROUND, & CO., Fibre Works, West Ferry Road, Millwall, London, E.

GARDEN REQUISITES.—Cocoa-nut Fibre Refuse, 3d. per bushel, 100 for 20s., truck (loose), 30s. Light Brown Fibrous Peat—5s. 6d. per sack, 5 sacks 25s., 12 for 45s., or 80s. per ton. Black Fibrous Peat—5s. per sack, 5 sacks 22s., 12 for 40s., or 34s. per ton; sacks 4d. each. Coarse Silver Sand.—1s. 9d. per bushel, 15s. half-ton, 28s. per ton; in 1 cwt. bags, 4d. each. Yellow Fibrous Loam, Peat Mould, and Leaf Mould.—1s. per bushel. Sphagnum Moss.—8s. 6d. per sack. Manures, Garden Sticks, Virgin Cork, Tobacco Cloth and Paper, Russian Mats, &c. Write for free Price List.—H. G. SMYTH, 17a, Coal Yard, Drury Lane (late of Castle Street, Long Acre).

THE SUB-TROPICAL GARDEN has beautifully-engraved figures of all the important types of hardy plants useful in obtaining picturesque effects in the garden. Price 5s.—GARDEN Office, 37, Southampton Street; and through all booksellers.

GARDEN NUISANCES.

FREQUENT discussions have taken place in GARDENING ILLUSTRATED on the above subject, but I have not found that anybody has discovered the perfect cure for any of them. Perhaps the experience of an old gardener may be of further use. The remedies given are what I now always adopt when patience is severely tried, and measures of some kind must be taken. We will begin with

Cats, and their mischief of rolling upon favourite plants and scratching holes. There is no use whatever in destroying them ; apart from its being an unjustifiable and cruel act, either to kill or trap them, it is useless, because others will be sure to take their place ; nor is there any occasion to banish them altogether, as if they cannot roll or scratch up a plant, any number of cats might be in a garden without injury. Most people who have gardens know the plants which cats delight to roll upon, but they will go to any newly planted subjects, as Pansies, &c., because the ground is loosened and makes scratching easier to them. Therefore, when any choice plant is bedded out, cut a few sticks 8 in. or 1 ft. in length and thrust them firmly in round the plant, allowing the pointed ends to stand outwards, five or six such sticks will secure any plant from further molestation. I always keep my old Raspberry canes for this purpose. If cats have only one or two places of entrance to a garden, and that from walls or other projections, a great deterrent is coal gas tar liberally painted about ; they have a great dislike to it, but it requires renewal when dry.

Caterpillars generally are not so effectually prevented ; but the best cure is soot. If this is thrown about Currant or Gooseberry bushes about this time of the year, one or two dressings will suffice ; it will be found to destroy them altogether, and if it is lightly dusted over Cabbages in summer, with a large tin having holes at the top, it will be very effective.

Slugs.—To destroy these is a far more difficult matter, and I confess, although I have adopted the following treatment for them, that it is an incurable evil, but can be mitigated to some extent. The first procedure is in winter, at that time during frost. Turn over the frosty surface, that is, turn the frozen surface downwards ; it can easily be done with a stout fork ; apply soot then over the surface. In spring, dress the surface and about the plants with lime and sand, distributed with a canister and holes as before. In summer when the leafage of beds is too thick to apply these dressings, which are also unsightly, clear lime water is the best of all, but the lime must be fresh and allowed to settle before use. It may be used with a watering-pot and will neither disfigure nor injure anything ; if done twice a week in the evening, it will be almost a cure for these miserable pests.

Wireworm is a still more difficult subject to treat of. I can state confidently, however, that guano kills them ; fortunately, they are not found in any ground that has been cultivated for some years. All gardens recovered from waste land are full of them. If such gardens are well dressed with guano they will soon disappear. In potting loam it is very common. When I get this from a forest in the neighbourhood, I always water it well with strong guano water besides searching for these ruthless destroyers ; and fortunately they are easily seen from their bright yellow colour. W. T.,

Dorset.

GARDENING FAILURES.

FIRST, let "Disappointment" (p. 533) obtain all the back numbers of GARDENING from October 23 last, and carefully read therein the articles on Town Gardening. They were written expressly to meet such difficulties as his. Outdoor plants have already been treated of, and the management of window and greenhouse plants will be given in future numbers. He may rely implicitly upon all the instructions given in these papers. The varieties of plants recommended are the result of a long experience in a much worse locality than Camberwell.

In the meantime, here are a few hints. Is "Disappointment's" garden too shady? As that would account for a paucity of bloom. If enjoying a fair amount of sun the soil may be wrong in some way. If this is too poor, manure it well with rotten, not fresh, manure ; if too wet, drain it ; if too dry, renovate it. As for sparrows, there is nothing like strong black cotton, stretched a few inches above the things to be protected ; the birds cannot see this, and it entangles and alarms them. Then remember that Camberwell is not like Kent or Sussex, or any open country place ; there all you have to do is to plant things. They are sure to grow ; but in town and suburbs you must make them grow by constant care. Geraniums ought to do well ; their running to leaf to such an extent suggests too rich a soil. Try sinking the plants (in 5-in. pots) in the soil. For suitable annuals, &c., see the lists given in the number for November 20 of last year. Corn-flowers, Phlox Drummondi, Mignonette, and Indian Pinks could scarcely fail in any case.

Regarding the greenhouse, the air within it has evidently been allowed to become too dry and parching. If "Disappointment" really wants to succeed, and have flowers in winter, let him discard the hot-air arrangement, and have hot-water pipes fitted, heated by a slow combustion boiler, which he will find far more satisfactory and economical, and far less trouble than anything else. Keep the atmosphere moderately moist by sprinkling the floor, paths, &c., not the pipes or plants (or these last but seldom). 60° is too high ; 50° or 52° by night, 55° on a dull day, 60° or more on a sunny one, is plenty at this time of year, and will produce plenty of flowers, with care in watering. You cannot grow Heaths in Camberwell, and I would say, stick to Geraniums and such comparatively hardy things until the first principles of success have been mastered, and do not attempt Camellias, &c. ; above all, keep everything perfectly clean from both insects and dust.

As it may be some time before the lists of greenhouse plants appear in GARDENING, I may mention a few things that would do well with ordinary care. Those marked with an asterisk need more attention than the others.

Geraniums (flowering zonals, not bi or tricolors) ; Pelargoniums, show and fancy ; Calceolarias, shrubby ; ditto, *herbaceous ; Campanulas ; *Cinerarias ; Primulas ; Petunias ; Plumbago capensis ; Hyacinths ; Tulips, &c. ; Fuchsias,—get Mrs. Marshall, Sedan, Try Me O ! and Wave of Life to begin with ; Ferns, such as the varieties of Asplenium and Pteris, Mimulus, Balsams, Myrtles, Ficus, and a few Genistas. You can scarcely go wrong with these.

If still at fault, I can give still farther directions, but a few more particulars would be needed. B. C. R.

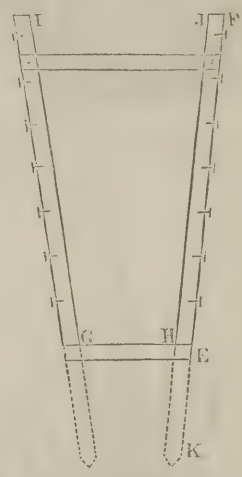
Ridging Ground in Winter.—There is no method which more effectually brings garden soil into a healthy state than laying it up in ridges during the winter season. This system possesses a two-fold advantage, inasmuch as when the planting season arrives, it is known to be in a sweet condition ; and by readily throwing off the superfluous moisture it is more easily brought into working order. On soils of a stiff, tenacious character, ridging is indispensable, but it may be safely affirmed that all kinds of soils would be much benefited thereby. If a very neat and trim appearance is indispensable, then in most cases I would prefer to merely clear the ground and let it lay untouched until the beginning of March. Freshly dug ground would appear to retain an undue amount of water, which has the effect of rendering it pasty and sour. This more especially applies to rich alluvial soils, and I have often noticed that where the surface has been left untouched, and even covered with weeds, the soil will, when dug in the spring, appear much more mellow and be in far better working order than that which has been carefully dug over. I would therefore recommend either throwing up fallow ground into rough ridges (the rougher the better), or letting it alone altogether. Simply digging I consider a mistake, and whoever desires to ensure neatness thereby must expect that he will experience a great amount of labour to bring the soil into that sweet, friable state which in vegetable culture is the very mainspring of success.—H. C. S.

Raising Small Seeds.—Small seeds, such as those of Lobelia, Begonia, &c., occasionally present, especially to the amateur, considerable difficulty in inducing them to germinate. This arises from the fact that, while it does not do to cover such seeds with soil, a very small amount of surface dryness is sufficient, when the seeds are swelling, to destroy them altogether. Covering the pots with Moss or sheets of glass is occasionally recommended ; but both tend to draw up the seedlings, and not unfrequently cause them to damp off. Such being the case, I submit the following plan, with which I have been very successful in raising hybrid Begonias, whose seed is very small indeed. In most plant houses may be found pots surfaced with a delicate growth of Moss, varying from the condition of a green felt to fully-developed Moss. On this sow the seeds. The Moss maintains a genial moisture, while its fibres retain among them the tiny seeds and prevent them from being washed down into the soil and lost. A piece of turf (peat) kept close and moist under a bell-glass also answers the purpose, but air must be freely and judiciously admitted as soon as the seeds are up.—G. P.

SUBSTITUTE FOR PEA STICKS.

THINKING that the plan which I have adopted (I may say invented) for the support of my Peas, and which I have satisfactorily and practically tested for two summers, may be of use to many readers of GARDENING who have difficulty in procuring sticks, I beg herewith to give an account of my system with diagram of the same.

For early Peas, such as Emerald Gem and Ringleader, &c., the standards are 3 ft. in height out of the ground from E to F ; 7 in.



between G and H, and 11½ in. between I and J. For taller-growing and more branching kinds I use standards proportionately larger in every way—*i.e.*, for Veitch's Perfection and Dr. McLean. My standards are 4 ft. in height, 9 in. between G and H, and 15 in. between I and J, and these widths between the uprights would be sufficient for a 5-ft. Pea. I make my own standards, which any one who can use a hammer and saw can also do. The wood is of red deal, 1½ in. by 1½ in. ; the nails are called 2-in. galvanised iron clouts, and have good large heads which are quite necessary. The bottom nail is 3 in. from the surface of the ground, the second 3½ in., the third 4½ in., and so on, the space between each increasing as we advance towards the top. I use "tarred band" nearly as thick as an ordinary penholder. Two strong pegs and straining cords, one at each end standard, are quite indispensable, as the band shrinks with the wet, and in so doing would pull the whole fabric down. Pieces of board the width of the standard are placed under the bottom bars of the end standards to prevent over sinking. The supports are fixed about 7 ft. or 8 ft. apart ; a loop is then made on the end of the band and slipped over the bottom nail, and you proceed to walk up and down each side of the row, giving a turn round each nail as you come at it. The operation is simple and expeditious, and you may string as few rows as you think proper, or you may continue and complete the stringing. With care the materials will last for years. EBORACENSIS.

EVENING PRIMROSES.

(ŒNOTHERAS.)

IT would be better were a more fitting designation found for a portion of this fine family of hardy perennials, which can scarcely be termed as of the evening, seeing that they expand in the full blaze of the sun and close again at dewy eve. The Evening Primroses are distinguished by large bright yellow or white flowers, which in many of the species are so freely and continuously produced as to render them of great value for the summer decoration of the outdoor garden. The Missouri Evening Primrose (Œnothera missouriensis) is often employed as a bedder, its blooms being of large dimensions, and the habit of the plant dwarf and spreading, thus rendering it suitable for beds on lawns or for associating with other dwarf-growing subjects. This species demands for its well-being a warm, well-drained soil, growing with great freedom when thus situated, and not needing the slightest protection in winter. When, however, the grower may have to contend with a cold, moisture-holding soil, he will find it imperative to take some precautionary measures at the commencement of the winter months. The best way to treat this plant is to take off some cuttings during the summer months, which strike freely if inserted in sandy soil in a sunny situation.

The soil should be thoroughly pulverised by turning it up roughly some time previous to putting in the cuttings, and should be well stirred with a fork and every lump broken. Then, having raked the surface and made it smooth and even, draw some shallow drills say 3 in. deep, and nearly fill them with fine sandy mould. Press this fine compost firmly down and insert the cuttings therein, giving them a good watering to settle the soil well around them. Should the weather prove very hot and dry, stick in a few branches of evergreens in such a manner that the cuttings are shaded during the hottest portion of the day. Otherwise as little shade as possible should be given, for this Œnothera is of rather succulent nature, and enjoys the full blaze of the sun. If a cold frame is at liberty the young plants may be taken up in the autumn and laid in in some light soil, where not only will their safety be secured, but they will make throughout the winter a large amount of fibre, and will be in prime order for planting out in the spring. Young plants thus treated will generally give more satisfaction than stools which may have passed the winter in the open ground, for the flowers, if not produced in greater profusion, will be individually much finer.

Where the accommodation of a glass roof cannot well be accorded them, their safety will be assured by bending some Hazel rods over them and covering during periods of inclement weather with a mat or two; or, in the case of isolated stools, the crowns may be covered with Cocoa-nut fibre, ashes, or some kind of litter, or, better still, a large flower-pot or cloche. It is when the ground has become soddened with rain or snow and severe frost sets in that this, as well as many other so-called hardy plants are liable to receive an irremediable injury. If the plant is not killed outright its vitality is so sapped, that when the growing time comes there is an almost entire absence of that luxuriant vigour which characterises this species when the functions are in an active, healthy state. Where the natural staple is of a free, warm, sandy nature there is no need to take any of these precautions, as the roots and crowns will remain in a perfectly healthy state throughout the year, quite unaffected by extremes of wet or frost.

There could scarcely have been a more trying winter than that of 1879-80 for plants of such a nature as this one, but in spite of the unusual severity of the weather, extending, as it did, over so long a period, I did not perceive that a single plant suffered any diminution of vigour where the natural staple was light and well drained. This proves that this Evening Primrose is perfectly hardy providing that excess of moisture can be guarded against, but where any doubt upon the point exists it will be better to adopt the means above suggested, and which the writer has proved to ensure the very best results being obtained from this extremely gay perennial. A species which offers a decided contrast to the Missouri is Fraser's Evening Primrose. This kind throws up a number of erect, somewhat rigid stems, some 18 in. high, terminating in dense clusters of large yellow flowers, which are produced continuously for several months. This species, in common with some other nearly allied to it, possesses points of beauty not always noticeable at the first glance. The contrast between the rich golden hue of the flowers, the beautiful green glossy foliage, and the rich warm brown of the flower stock is very pleasing, and affords a harmonious combination of colour but rarely met with in flowering plants.

Fraser's Œnothera is a hardy kind, perhaps the hardiest of the genus, for I have known it to live and thrive under circumstances which must have proved disastrous to the major portion of this family. I would, therefore, recommend this species to the notice of all plant lovers as being calculated to give a large amount of pleasure for a very small amount of labour and expense. As a complete contrast to the foregoing, I would take either taraxacifolia or marginata, the latter a lovely kind, and worthy of a place in the most choice collection of hardy perennials. Other yellow-flowered kinds consist of riparia, a species much resembling Fraseri, but less vigorous; serotina, and Youngi. In all cases, and wherever these Evening Primroses may be grown, it should be remembered that they, being profuse and continuous flowerers, demand a rich, free, deep soil, where during the hot and trying months of July and August they may find, just when there is the greatest strain upon them, an ample store of food and moisture. Upon the previous careful and thorough preparation of the soil depends the enjoyment derivable from this fine, but, I may say, much neglected family of hardy perennials. An impoverished, sour, or clogged soil, in which the roots cannot travel freely or exist in comfort throughout the year, can only be productive of disappointment. Dig deeply, expose the top spit to sun and air, add light soil where such is seen to be necessary, manure well where there appears to be a lack of nourishment, and you will get for some months in the year a fine display of beautiful flowers.

J. C. B.

Missouri Evening Primrose (Œnothera missouriensis).

Large-flowered Evening Primrose (Œ. grandiflora).

Dandelion-leaved Evening Primrose (Œ. taraxacifolia).

Lamarck's Evening Primrose (Œ. Lamarckiana).

Drummond's Evening Primrose (Œ. Drummondi).

Handsome Evening Primrose (Œ. speciosa).

Phlox Drummondi grandiflora.—Nothing can exceed the beauty and usefulness of this Phlox, either as a border plant or for bedding purposes, and it is also invaluable for furnishing cut flowers. Its colours, which are varied and brilliant, are far superior to those of the older varieties, and they are not injured by bad weather or frost like those of many other flowers. Although this Phlox is generally treated as an annual, it strikes freely from cuttings in autumn; these come in usefully for pot culture and early spring bloom in the conservatory or greenhouse. Seed should be sown in

February or March, and the plants be grown on for planting out early in May or June.—W. D.

A Few Words on the Mesembryanthemum.—The Mesembryanthemum is classed among greenhouse succulent plants, but to see some of the most hardy sorts growing out-of-doors all the year round at Scilly and in Cornwall, one might be apt to think that the above-mentioned places were their real native lands. But when we investigate the matter more fully and find that a great many of them come from the Cape of Good Hope and such like places, it is rather startling. At the islands of Scilly in the month of May the rockery is all ablaze with these beautiful flowers, and is one of the best sights to be seen of its kind. The Mesembryanthemum is one of the finest families of plants one could put in a rockery. Some of them are very rank growers, covering in a comparatively short space of time a large space of ground. But this is a very good fault if it can be so called, because in the month of May they can be easily cut back to the required size without injury to the plant. They are also very suitable for hedges or walls, looking green in the winter, when almost all other plants are bare, and gay and brilliant in the summer. Indeed, as I have said before, nothing is more suitable for a rockery than this kind of plant, its mass of flowers looking so brilliant and dazzling in the summer, and its green, fleshy leaves in the winter. All the sorts may be had from seed, and most of them by cuttings about May, dried at the base before inserting them in sandy soil, peat, loam, lime rubbish, and old cow manure well drained. Seeds should be sown in a hotbed, and the plants be gradually hardened off before being planted out.—H. ROBERTS, *Gulval.*

Planting Ixias, Sparaxis, &c.—Now is the time to plant Ixias, Sparaxis, Babianas, and similar Cape bulbs, which, unless planted early, do not bloom in such perfection as they otherwise would do. They should be planted in rows across 4-ft. beds, 2 in. deep. Dig up the soil in the beds loosely, and on no conditions trample on it, and some rough sand should be strewed in the notches under and over the bulbs at planting time. The sand is not only beneficial to the bulbs, but it is also useful in showing where they are at lifting time, when, from being so small, they are otherwise often overlooked. Of course the ground should be in workable condition, not frozen or full of snow. —F.

VEGETABLES.

HOW TO GROW GOOD RADISHES.

IT is necessary that some pains should be taken to insure a free and moist root-run in well enriched ground if Radishes are to be grown in perfection. It is often customary to sow them and other salading indiscriminately in any piece of ground which may happen to be in readiness or become vacant. This is, however, a mistake, as the soil, from being partly exhausted by a previous crop, and perhaps become somewhat lumpy and sour, is in a very unfit state for the reception of the seed. It would be much better if, at the close of the year, a spot of ground were selected and retained for this purpose alone during the ensuing summer. It could then receive careful preparation, and would be always in readiness. This latter point is not the least advantage which would accrue to the grower from an early preparation of the soil, as a break in the supply will sometimes occur through not being able to sow in time. The most suitable soil for the Radish is that which can at any time be easily and freely worked with the fork. A light and somewhat sandy soil, that has been well enriched with rotten manure, will best promote the free root action which it is so necessary to secure, and without which tender and well-flavoured Radishes cannot be grown. If the soil should therefore be as above described, it will be easily sweetened and pulverised by well stirring it with a fork; it will then only be necessary to afford a liberal supply of nutriment during the growing season. This is best accomplished by working in a good portion of thoroughly decomposed manure; that which has been used for hotbeds, and which has been turned over several times, is admirably suited for the purpose. Lacking this, short stable manure may be employed, removing the straw thoroughly, breaking all lumps, and working it in to at least the depth of 1 ft. Should the soil be of a stiff, tenacious character, add a good portion of leaf-mould, wood ashes, or any light material which may be obtainable. During the winter the ground should be ridged up, and should remain in that condition till February, when manure should be added, and it should then be half trenched, burying the top 6 in., and bringing about the same quantity up in its place. This should be laid up as roughly as possible, in order that it may become thoroughly sweetened by the time when it is required for use. Manure may again be added at discretion. A good depth of free, well-prepared soil will thus be secured, and the extra pains bestowed on its preparation will not be regretted, especially if a hot summer ensue. In shallow or unsuitable soils, a few days' hot sun burns up the fibres, and watering is almost useless. This is mainly the cause why hard, dry, sticky Radishes are more the rule than the exception. Where a good deep root-run is provided, water may be given with beneficial effect, and a good soaking now and then will suffice to keep the plants growing without check. It is from the beginning of June onwards up to the end of August that the greatest difficulty is experienced. It is, however, comparatively easy to have good tender Radishes at any time, provided the requisite precautions have been taken to promote free root action. Frequent sowing is, of course, indispensable, and this operation must be so conducted as to preclude the possibility of failure in germination. If the weather be hot and parching, the best way is to well water the ground at night, and early in the morning sow the seed thereon, which should have been previously soaked for twenty-four hours and mixed with sand, to admit of its better distribution. Cover with some light soil, which should be firmly pressed down, and then lay some boughs or old Pea-sticks over the bed. Quick and free germination will thus be secured. If sown broadcast, 4-ft. beds are the most convenient size, as the plants can then be easily thinned and weeded; or they may be sown in drills about 9 in. apart. Of the two methods sowing in beds is, however, rather the best, as the Radishes can there be more easily drawn when fit for use. W.

Common Evening Primrose (Œnothera biennis

How to Grow Parsley.—Parsley should be sown about the end of February or the beginning of March on well pulverised land in drills 1 in. deep and 1 ft. apart. It may either form an edging to another crop or occupy a bed or patch by itself. When large enough, thin out the plants to 4 in. apart. Another small sowing should be made about the beginning of July, and be thinned out and treated the same as the early-sown lot. Parsley sown early, and required to be gathered of a moderate size, becomes pretty well exhausted by the following spring, and hardly any precaution will prevent it rushing into flower before the new crop may be considered fit for gathering. But the crop from a midsummer or July sowing comes in at a season when everything is full of growth, and has a chance to get thoroughly established, and this is one advantage in favour of the permanency of the plant. Another and the main reason that may be advanced in favour of this time for sowing is, the plants have not the same tendency to flower and seed he following sesaon. Any one who has hitherto depended upon the early spring sowing, and has found a difficulty in making the two crops meet, should try this plan. Strictly speaking, Parsley is a biennial, and if sown after midsummer, its season of flowering will be proportionately late; and this is a great advantage when plants are grown for their foliage alone. Some means of sheltering the crop should be devised and prepared before bad weather sets in. Straw hurdles or forked sticks may be placed round the bed on which other pieces are placed, when the whole may be lightly covered with Fern or dry straw.—H.

Lettuces in Pots.—Every one would like a Lettuce at this season of the year, yet few people get them. It is, however, neither troublesome nor difficult, nor does it involve much extra expense, and where a large supply of salading is required, the results obtained in this way are so certain, that the method should be adopted more often than it is. The plants will do very well in an orchard house, but of course will come on faster in a warm house, such as a Vinery or Peach house. Although they will stand a stong heat, from 50° to 60

suit them best, and, in fact, will give range enough to show how accommodating they are. When grown rapidly in a light house, they are more tender and more delicate in flavour than when exposed to all the vicissitudes of temperature and other unfavourable circumstances in the open air, no matter how sheltered and protected they may be. There is no fear of snails or slugs eating their hearts, and neither is it necessary to smother them with lime or soot, in order to keep these depredators at a distance. A 4½-in. pot will hold a good large Lettuce, and a couple of hundred, more or less, will not occupy much room. This number will furnish a good many salads. Tying up for blanching, as they become large enough, and supplying them with water, are the chief operations required in connection with the undertaking. It is always advisable to grow two or three kinds. The Tom Thumb is a beautiful small Cabbage, and will come in before any other kind. The White Paris Cos or any good variety of it will come on in succession, and the Dutch Cos may always be relied on to do well under any circumstances, both indoors and outside. It will probably take longer to blanch, but will keep longer in that condition afterwards.—H.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

January 24.—Finishing the digging of vacant ground making ready to sow a second piece of Broad Beans (Early Long-pod); digging flower borders and among standard Roses; sowing Dutch Turnips, Peas (consisting of Laxton's Alpha, Little Gem, and Advancer), Spinach between the Peas; potting cuttings of Calceolarias; potting some young Vallotas; putting a few scented Verbenas into heat for cuttings; putting in Red and Black Currant and Gooseberry cuttings; planting Potatoes under south wall, and sowing a few Radishes among them; beginning to layer Carnations for flowering in winter; wrapping Ageratums in Moss and putting them in boxes in heat, so as to be able to divide them at bedding-out time; shifting herbaceous Calceolarias into good rough material; cleaning scale off Camellias; making another frame ready for Carrots and Radishes; getting all Peach trees pruned that are under glass; cutting down the winter Heaths which have done blooming; finishing the pruning of wall and pillar Roses; also that of bush fruits.

Jan. 25.—Digging among Currant trees by walk sides; sowing Cabbage Lettuces; also Cauliflowers in frame; potting off late-struck Christine Pelargoniums; also Vallotas, Amaryllis, and Eucharis; putting one-year-old Vines into fruiting pots; putting in Bouvardia cuttings and cutting down old plants; putting in another crop of Rhubarb; shifting Humeas; putting all Fuchsias into heat; getting all Vines painted and tied down; fumigating Pelargoniums and Roses; giving Vine border a top-dressing of burnt refuse, ashes, loam, old mortar, and farmyard manure.

Jan. 26.—Sowing Walcheren and Loudon Cauliflower in heat; also Lobelia speciosa in heat, and more Syon House Cucumber; beginning to shift Centaureas into 8-in. pots; putting in Petunia and Verbena cuttings; placing old Verbenas in heat for cuttings; planting Jerusalem Artichokes with leaf soil; putting in Endive to blanch weekly; placing Crocuses and Snowdrops in cold pits; fumigating Gardenias.

Jan. 27.—Sowing Capsicums, Tomatoes, and Carrots on leaf beds; also Lobelia in heat; beginning to box Balm; potting Tigridias and placing them in Peach-house; also Tuberoses and plunging them in heat; giving Gardenias some Standen's manure, and afterwards watering them with guano-water once a week; putting in Verbena cuttings; also some cuttings of Poinsettia, Heliotrope, Achyranthes, Salvia fulgens, Fuchsia, and Lobelia speciosa; planting Roses where needed; tying down Raspberry canes; manuring and just pricking over the Asparagus beds; clipping Privet and Yew hedges; thinning Radishes in frames; placing all Potato frames on leaf beds and putting in soil.

Jan. 28.—Sowing Radishes and Carrots in frames; also Incomparable and Ivery's Celery; potting Isolepis, Selaginella, and Cucumber plants; potting Lælia superbiens in nearly all Sphagnum, the pots being crocked to the top; shifting a few young Fuchsias and putting them into second Peach house; beginning to nail Apricots; putting gas tar round Violet frames and stopping up all rat holes; washing Daphnes; getting soil and pots into warm for Beans; loosening the Peach trees on walls; beginning to prune Apricots and Peach trees; cleaning herb beds.

Jan. 29.—Sowing Orangefield and Kaye's Tomatoes; potting some Oxalis and autumn-struck Heliotrope; also some Centaurea cuttings, and putting them into Peach house; putting in cuttings of Cineraria maritima, Carnations, and Scented Verbenas; planting out the first Cucumbers in five-light pit; layering winter Carnations; turning manure for Celery; putting some manure on Rhubarb out-of-doors to blanch; also on Seakale; making new Horseradish bed, taking up old stock in order to be able to prepare ground.

Glasshouses.

Epacrises.—There are numbers of these naturally disposed to bloom in the winter, but they flower much freer and fuller if placed in a temperature such as conservatories are ordinarily kept at this time. Amongst them are the erect-growing varieties of E. hyacinthiflora, candidissima, carminata, and fulgens. In the more bushy-habited kinds the white Lady Panmure, Salmonia (salmon colour), and Sunset (fiery red), with others of intermediate shades, will, if accommodated with the little extra warmth, open their flowers much freer than when kept cool, and continue blooming for many weeks. They are much more generally useful than winter-flowering Heaths, on account of their being more easily kept in health, giving greater diversity of colour, as well as brighter and more cheerful-looking blossoms, and better adapted for cutting. With the erect-growing kinds especially it is necessary to considerably reduce the preceding season's growth; consequently, the whole of the shoots have to be shortened back, and they may, where cut flowers are wanted in quantity, be so treated whilst in bloom. The bushy growers will also bear the knife freely. For the same reason there need be no hesitation in cutting their shoots when in flower.

Acacia armata and Drummondi.—If the plants have made their growth early in summer and are well ripened up, the temperature of the conservatory will bring them on into bloom quickly, and the flowers will last longer than if developed in more heat. Both these Acacias, when they have attained anything near the size required, will be benefited by three-fourths of the current season's growth being reduced.

Daphne indica.—This is another plant which should find a place in every conservatory, as its presence alone, without the aid of any other sweet-scented flowers, is sufficient to keep up the most agreeable perfume. Both the white and the pink bloomed varieties deserve growing. Their agreeable scent is frequently the cause of more of their flowers being cut than is consistent with the well-being of the plants, which cannot bear much cutting, unless, in the case of individual specimens that are very strong, and in this matter the cultivator can always be guided by the condition of the plants.

Oranges.—Where these are treated so as to keep them in a healthy, vigorous, thriving condition, furnished with plenty of good deep green-coloured foliage, they are amongst the most effective and useful subjects that can be introduced into a conservatory, bearing fruit in different stages of development for a great portion of the year, and producing plentifully flowers alike acceptable for their odour and also for cutting. There is one drawback to their cultivation, their liability to the attacks of insects, particularly brown and white scale. Where the latter exists on large specimens it is impossible to keep them in health without continual attention. Now whilst they are dormant an effort should be made to get these pests well under; they may be altogether eradicated by repeated dipping or syringing with strong insecticide, but to accomplish this it will often be found necessary to sacrifice the flowers for a season, as the continued washing with a solution sufficiently strong to destroy these most difficult of all insects to kill frequently has the effect of stopping the development of the bloom-buds, but the loss of a season's flower will be found to be amply compensated for by the improved after condition of the plants and the great saving in labour. In small conservatories a few medium-sized plants of the ordinary sorts of Orange will associate well with Camellias, and the small-growing Otaheite kind that fruits so freely when not more than 12 in. or 15 in. high will be found suitable for standing in vases on brackets, or other prominent positions in either large or small houses.

Correas.—Amongst smaller-flowering hard-wooded plants that keep on blooming for a considerable time, and are well adapted for conservatory decoration, are several of the varieties of Correa, of which may be mentioned C. cardinalis, C. brilliant, and C. bicolor. The blooms last long on the plants, and, hanging gracefully as they do from the small slender branches, will be very useful in combinations of cut flowers.

Kalosanthes.—If cuttings of these are put in at once time will be gained, as, if subsequently fairly treated, good blooming plants may be had in eighteen months. Cuttings can be got from any established plants, selecting the strongest shoots that are not going to flower, which will be easily discernible, putting three or four together in small pots in sandy soil and placing them anywhere where the temperature is a little above that of an ordinary greenhouse, but not enclosed under a bell-glass or propagating frame, which, in their case, is unnecessary. Moderate-sized plants in from 8-in. to 10-in. pots are the most serviceable. Those that are intended for flowering the ensuing summer should now have their shoots regulated with a few stakes and ties just sufficient to keep them in an erect position.

Boronias.—B. Drummondi and B. pinnata will be now coming into flower, and will keep on blooming through the winter and spring. B. elatior and B. megastigma, comparatively new kinds, are both beautiful, and B. serrulata, later in its flowering, is most desirable on account of its perfume; a small plant in a 6-in. pot will agreeably scent a large house. If a few of these plants are grown for interspersing about the greenhouse or conservatory, their distinct drooping habit will do much to relieve the oversameness of Pelargoniums, Fuchsias, and the like. If kept in a low temperature at this time they are rather subject to mildew, but if accommodated with 40° in the night and a rise of a few degrees in the daytime, they are not liable to suffer in this way.

Chorozemas.—For a like purpose in giving variety these will be found of very easy growth, producing for a considerable time their brilliant flowers in profusion. If a few varieties, such as C. cordatum splendens, C. varium Chandleri, and C. varium nanum, are grown in moderate-sized pots, they will do good service through the spring months. Their healthy green foliage is little subject to the attacks of insects, except red spider. These plants will bear keeping cooler than the Boronias; the small amount of tying they need should now be done.

Epiphyllums that have had their growth well matured during the summer, by exposure to all the sun possible, should now be kept at the warmest end of the greenhouse with very little water at the roots, only just enough to prevent them from shrivelling too much, for if, whilst subject to a somewhat low temperature, the soil in which the small amount of roots they make exists is at all over moist, the fibres will rot, to which cause may be often attributed their not blooming freely. E. Ackermanni, E. crenatum atro-sanguineum, E. speciosissimum, and E. speciosum superbum are much more deserving of cultivation than many of the weedy subjects that now find favour. Plants of E. truncatum intended for late flowering to come on with just warm greenhouse treatment must likewise not have too much water at the roots until the advancing season affords more warmth.

Statices.—These are strictly greenhouse plants, but, at this time of the year, they should be kept in a temperature of from 40° to 45° in the night, as, unlike many other hard-wooded plants, they are never absolutely at rest, growing slowly through the winter; their roots are also continuously active; consequently, even at this season, they require the soil to be kept a little more moist than for most plants. There is one point in their cultivation that requires attention: the old leaves as they gradually decay do not fall off, as in the case of the generality of plants, but hang dead upon them, and if not removed when in this state, they are apt to go mouldy, and sometimes destroy the shoots to which they are attached.

Roses in Pots.

Tea Roses in pots grown out-of-doors in summer and treated with the intention of having them well furnished with buds in the autumn, and then placed in a greenhouse temperature to enable the full development of these outdoor formed buds without much fire-heat, which they will do up to the close of the year, will now need to be managed with a view to their doing service in a like manner next autumn, for, when required to produce flowers in this way there should be no attempt to force them on so as to make further growth and bloom after they have borne the first crop; but they ought not to be turned out for some time yet into cold frames where the soil about their roots will be liable to get frozen, unless precau-

tions are taken to prevent this, as such treatment would affect their now more or less active roots and interfere with the growth they are expected to make during the summer. They should be put where there is the means of excluding frost, and any pruning that may be necessary it is better to carry out at once, allowing them to remain here until the spring, by which time their young shoots will begin to move, and whatever potting is needed can be done, and when the season is past for any frost likely to injure them, they may be turned out-of-doors where they are to remain for the summer with their pots plunged in ashes. Where there is an attempt to supply Roses all the year round, plants thus treated fill an important place, their bloom coming in before that of those subjected to more heat, but if they are to increase in size and vigour, as is desirable, they must even now, after flowering, be cared for in a manner different from the rough usage to which they are often submitted when their blooming is over.

Strawberries in flower should have the pollen distributed daily, and air given freely whenever the air outside is free from frost. Keep the plants reasonably moist, and avoid splashing the flowers with water. As soon as the fruit is set, thin it out to six or at most eight fruits to each plant, after which manure water may be given twice a week. Successional batches of plants should be placed in warmth fortnightly in order to keep up a continuous succession of fruit till open air crops are ripe. As a rule about three dozen plants put into warmth fortnightly will ensure a moderate succession of fruit. Shelves for plants that are to remain in the one position till their fruit is ripe may have a coating of horse droppings or turf cut the width of the shelf, and laid Grass side downwards; into this the roots soon find their way, and much labour is saved, as water is not so frequently required as it otherwise would be. The plan has one drawback only, and that is, the drainage sometimes gets choked, a matter easily avoided.

Melons.—Do not be in a hurry to plant these out. At this early season there is little danger of their being pot-bound, and the plants will make better progress if kept on shelves near the glass for another week or two than planted out. The soil should be got in to admit of its getting warmed through thoroughly. Moderately stiff loam, without any admixture whatever, is best, and if fresh dug from the pasture all the better. It should be well pounded when put in the bed, and the lighter the soil the harder should it be made. Make another sowing in the manner recommended in a previous calendar.

Flower Garden.

Acacia lophantha, one of the most graceful and effective of sub-tropical plants should be sown now in order to have good plants for putting out in May. Another fortnight will be sufficient early to sow Solanums, Ricinus, Wigandias, Ferdinandas, and other free growers, as they are apt to get pot-bound and stunted before planting time when sown too early. Pelargoniums that were not propagated in sufficient quantity in the autumn should now receive attention; three cuttings in a 3-in. pot make fine plants for turning out into the beds without division. They strike freely at this season on a dry, warm shelf in a Vinery, where there is a minimum temperature of 55°. When the weather is open trench and dig all beds and borders that are vacant, and each bed should have manure proportionate to the requirements of the plants intended to grow in it. Calceolarias, Verbenas, Violas, and all sub-tropical plants can scarcely have too much. Pelargoniums flower best when the soil is poor, but the beds should be deeply trenched with the view of resisting drought. Well roll all walks immediately after a thaw; they will dry off hard and smooth, but if left till dry the roller makes little impression on them. Complete re-gravelling or re-surfacing and turning walks as the weather permits, in order that they may get consolidated before a drier period arrives. The same remark applies to lawns, which at this season can hardly be rolled too much.

Fruit.

Vines.—All Grapes now on the Vines should be cut and stored in a dry room, for if not done soon, a recurrence of mild weather will at once put the sap in motion, and two evils will be the result, viz., the Vines will bleed by being pruned so late, and the Grapes will burst as soon as they are put into the bottles of water. When the pruning is done thoroughly cleanse the houses and Vines by rubbing off any loose bark and painting them with the usual composition, both as a preventive against and remedy for insect pests. The borders should then be renovated by clearing off all surface soil, working it out from the roots with hand-forks, and replacing it with the best loam that is to be had, with which should be mixed a liberal allowance of ½-in. bones and wood ashes or charcoal, the whole being pressed firmly about the roots. For the present guard against exciting the Vines into activity by keeping the house as cool as possible, a month's real rest being more beneficial than twice that amount of uncertain rest.

Peaches and Nectarines. — Houses now being started should have the borders examined as to moisture; if dry, soak them well with tepid water. Outside borders should have sufficient protection to exclude frost, snow, and cold rains, but artificial warmth is neither necessary nor desirable. Let late houses have the necessary pruning and cleansing on the first opportunity, and induce effectual rest by keeping the temperature at the lowest point commensurate with the future well-being of the trees.

Vegetables.

Early Horn Carrots may now be sown, but in cold positions Carrot seeds lie a long time in the ground, and under such circumstances it will, for very early crops, be better to cut a wide trench, and fill it with warm manure; cover it with 5 in. or 6 in. of light soil, and protect it with glass or outer covering. Sow a few Wood's Frame and French Breakfast Radishes and protect them as suggested.

Where an autumn supply of Brussels Sprouts is required, a box or two should now be sown under glass. Plant out from the seed bed autumn-sown Cabbages to succeed those planted last September. Stir the soil with a fork between the rows of early Cabbages, selecting a drying day for the operation, and afterwards earth them up. Make a small sowing of Celery, in pans or boxes in heat, for flavouring purposes. When the weather is suitable, and the ground in good working condition, a portion of the autumn-sown Onions should be transplanted. Select for them a piece of land that was manured and deeply dug in the autumn or early winter; wheel on a good dressing of charcoal dust or charred refuse, spread it evenly over the surface, and rake or fork it in. Soot also may at all times be beneficially applied. Make the ground tolerably firm, and put in the plants, not too deeply, 1 ft. row from row, and 4 in. apart in the rows. Make a sowing of Veitch's Autumn Cauliflower in pans in heat. Take up the remainder of the crop of Jerusalem Artichokes; select the best for use; place them in a cool cellar or shed, with a little dry sand strewed over them to keep them from shrivelling.

As soon as the surface of the soil is dry enough, go over such crops as Spinach, Onions, Lettuce, &c., with the Dutch hoe. The sooner all vacant plots of land are trenched or dug the better. Sow early Peas in warm sheltered positions; Ringleader and William the First are suitable; or, for small gardens, Tom Thumb or Beck's Gem may be substituted. The dwarf Fan or Cluster Bean is a good companion for the Gem Pea; it is very prolific, and occupies little space. A few early Potatoes may also be planted in a warm position, but unless the means are at hand for protecting them when they come up, the chances of success are remote.

MY GARDEN FAILURES.

I WAS not at all sorry to hear the wail of anguish, from Camberwell, from the soul of a disappointed florist in GARDENING, 8th January, for it furnishes others with an opportunity to record their own experiences; and out of written confession of failure on the one hand, and chucklings of success on the other, much mutual instruction may be gained.

I, like the good-natured writer who styles himself an ass, am too an amateur florist, but am far from being—as he is—disappointed. On the contrary, though the hours I can devote to gardening are limited, and I commenced my labours with a very imperfect knowledge of the art, every step I take, impresses me more and more with the wondrous beauty and uniform action of Nature, as shown in the vegetable kingdom, and convinces me that no man, with a real love of flowers, need seek the help of others to produce them for the decoration of his rooms.

"Disappointment" asks that some kind friend will tell him in good round Saxon the cause of his repeated failures. They are, want of patience, perseverance, and attention; want of a stern determination to begin at the beginning, and understand, as far as a human being can do, the mystery of plant's growth. It is not evidently want of money. He has built a greenhouse upon a good plan, and he has the means to stock it, but he does not show wisdom by purchasing of a fashionable florist a quantity of first class plants to stock his greenhouse with. Does he not know that a fashionable florist pumps his flowers into bloom for sale? The Maiden-hair Ferns, Camellias, Heaths, Hyacinths, and Tulips supplied in full bloom from a nursery are not fit for stocking a greenhouse. "He who would have beautiful Roses in his garden," says the Reverend Canon Hole, "must have beautiful Roses in his heart. He must love them well and always. He must woo, though drought and frost consume. He must have not only the glowing admiration, the enthusiasm, and the passion, but the tenderness, the thoughtfulness, the reverence, the watchfulness of love." The love of flowers involves one in much labour, much anxious thought, requires great care, great assiduity, great circumspection, and crowns the patient worker with the proud satisfaction of having brought to the highest pitch of perfection the particular class or species on which he has delighted to expand his skill.

Some twenty years ago, when the volunteer movement was in its infancy, I strolled into Greenwich Park to see some young friends drill, and sitting at my ease on one of the benches, just as a sharp April shower had made way for a gleam of sunshine, I noticed these excellent fellows lying all about flat upon their stomachs on the wet Grass, pretending that an enemy was at the top of the hill, and they had to approach him cautiously; and I said, *sotto voce*, "You stupid asses! laying up a store of rheumatism for the indulgence of a whim—for the mere gratification of your hobby." But since then the successful cultivation of flowers has grown to be a hobby of mine, and only last Saturday as I lay at the bottom of my garden in the same position as the volunteers, picking out from an old frame some cherished lumps of rotten cow manure, my old words came back to me, and I laughed aloud at the recollection. My advice to your correspondent would be, clear your house of every fragile thing that your florist has supplied you with. Try to grow, and you will succeed in growing, any strong hardy plants first requiring comparatively little attention. Your interest in their culture will be gradually aroused; the experience gained will enable you to soar to higher flights, and you will live to sign yourself, not the "disappointed," but the "undaunted" one of Camberwell.

ZUM.

House and Window Gardening.

HOW TO GROW AN ACORN IN WATER.

I PROPOSE to give directions for growing Acorns in water, also several other plants in a similar manner. To begin with the Acorn: A Hyacinth vase, or, failing that, a pickle jar, is the best-shaped glass to use for the purpose. Choose a fine, healthy-looking Acorn, and crochet with moderately coarse cotton a little network case just large enough to bold it. Take off the cup and put the Acorn into this little bag point downwards, closing it at the top, and making a loop of cotton or chain stitch about 2 in. long (more or less according to the depth of the bottle) to hang it up by. Cut a narrow piece of wood of such a size that it will lie across the top of the jar without slipping in, pass it through the loop, and thus hang the Acorn point down-

wards in the glass, which must have just so much water in it that the tip of the Acorn scarcely touches it. Keep the bottle in a dark cupboard until the Acorn has sprouted, and then put it in the light, just as you would a Hyacinth, being careful to keep the water always at the same level. If properly managed, it will live for a long time.

It is very interesting to try to grow other plants in the same way. I have been successful in rearing an ordinary sweet Chestnut in water, giving it occasionally, by way of manure, one drop of ammonia (sal volatile). I cannot say whether the same stimulant would suit an Acorn. It is quite two years since my Chestnut was first started, and it seems quite strong and healthy, but of course very tiny, being only about 6 in. above the surface of the water. A Potato is well worth the trouble of growing in water, and should be managed exactly like a Hyacinth. From every eye will start a miniature Potato plant, and even tiny tubers will form underneath. It will not last so long as either an Acorn or a Chestnut; as soon as the nourishment contained in the tuber is exhausted, and the new ones are formed, it will gradually wither away. This experiment is a particularly interesting one to carry out, showing as it does, in broad daylight, the growth and development of the Potato, the greater part of which takes place underground in ordinary circumstances.

A Carrot grown in sand is, if well managed, a highly ornamental object. A good-sized and perfectly healthy root must be chosen, and if it has begun to shoot at the top, so much the better. Cut off quite evenly just the crown of the Carrot and place it on the top of the pot full of sand, covering the outer edge of it with a little more sand, so that the leaves look as if they spring directly from it. Moisten it well, and keep it in the dark until it has begun to sprout; be careful to keep it damp, and to move it into the light directly the leaves appear. If the cultivation is successful, an ornament pretty enough for any room will be the result, and which will have, to a novice, the appearance of a pot of Ferns. Another experiment, not quite so ornamental, but none the less curious, may be made with a Turnip, which, like the Acorn and Carrot, must be as sound as possible. Clean the outside, taking care not to injure the part from whence the leaves spring. Cut a piece off the bottom, and scoop out the inside, so that you have a hollow cup. Fasten string or wire to it, so that it can be hung to a peg upside down. Fill the cavity, and keep it filled with water. In a short time the leaves will begin to sprout, and will curl up round the ball of the Turnip, forming a pretty little hanging basket. Care must be taken to shift it occasionally, so that each side in turn is exposed to the light, or it will grow irregularly. These are only a few of the many experiments of this sort that may be made. Each and all point out their own particular botanical lesson, and no doubt much more is still to be learnt by careful and patient observation and experiment.—*The Queen.*

The Hart's-tongue Fern as a Room Plant.—The common Hart's-tongue Fern (Scolopendrium vulgare) is very ornamental, and it is a most interesting plant to watch, the fronds vary so much in breadth, in length, in texture, and even in shades of green, and the various stages of the development of the sori are very curious. I planted some about last April; each plant very nearly filled its pot, so there was very little earth. All have sent up two complete sets of fronds. I cut off any that become disfigured, and at the present time the plants are quite green, beautifully shaped, very glossy, and gracefully drooping. In order to make all symmetrical I fasten down slightly with hair-pins any fronds that are too upright. On some of them the sori, pale green, is just bursting through the epidermis, on others it is of a handsome shade of brown, velvety in texture, and extends quite across and far down the frond, which, when at this stage, has a tendency to grow sideways, so showing the under surface. All friends who see these plants on my dinner table or in my drawing-room admire them beyond measure. I give them a great deal of water nearly every day, let it run through the pots, and when there is rain I put them out-of-doors for an hour or so. They are placed about my rooms on side tables or anywhere; do not seem to want light. If the fronds get dusty and there is no rain, I dust them with a small brush. I am told gas does not injure them at all, but this I have not tried.—MARK.

Carrot-tops a Substitute for Parsley.—From autumn to spring being the time when Parsley is most wanted, both for cooking and garnishing, anything that will take its place, if only for garnishing, is a boon to those who have not Parsley in abundance. Now, an excellent substitute for it for garnishing is Carrot-tops. Let any one who has not Parsley sufficient for both purposes pot up a few Carrots, and put them in a little heat, and then nip the young growths off for garnishing. These, I think, will be preferred to poor Parsley, and will leave the genuine article more plentiful for cooking purposes.—J. H.

Moss on Lawns.—This is better not disturbed till early spring. It must then be torn from the ground with a long-toothed rake; and this should be done twice, allowing an interval of a week to elapse between the rakings. In the early part of March the ground should be dressed with good loam, with about a sixth part of lime added. It should be fine, so as to save the trouble of stone-picking, and then sow with a mixture of fine lawn Grasses.

Maurandia Barclayana.—This is a beautiful half-hardy climbing plant well adapted for the greenhouse window or balcony. It grows rapidly in rich, light, sandy soil, and bears a profusion of large violet-purple blos-

Maurandia Barclayana; a half-hardy climber, flowers purple.

soms. Seeds sown in March in sandy soil in a warm house or frame make good plants for flowering during summer and autumn. They must not, of course, be put out-of-doors till June, but for the window or greenhouse they may be planted in their flowering pots as soon as they are strong enough. Light, air, and sun are necessary to insure their flowering satisfactorily. In some warm counties the Maurandia will withstand the winter, but in most gardens it requires the protection of a frame or greenhouse.

FRUIT.

Gooseberries and Currants.—These are often grown in rows between the vegetables in kitchen gardens, or along the sides of the walks, as a hedge; but this is not a good plan, for they not only occupy more space when so arranged, but are far more difficult to protect from birds and vermin than they otherwise need be. One of the best arrangements which I have seen was planting all the early Gooseberries on an early Cherry wall border, and the late Gooseberries (Warringtons) on the Morello Cherry border; thus two birds were killed with one stone, for the same net protected both Cherries and Gooseberries, one side of the net being tacked to the top of the wall, and the other to a low rail in front of the border, but high enough to clear the bushes and permit a man to go underneath conveniently. The bushes that cannot be accommodated in this way should have a quarter to themselves. Gooseberries may be planted so close as nearly to touch each other, but Currant bushes should be allowed 5 ft. or 6 ft. between the rows. At first, however, young trees may be planted twice as thick as this, and every other bush can be removed and planted elsewhere when they get too crowded. For protection, the best and most economical way is to run a rail round the quarter, 5 ft. from the ground, with other rails at intervals between, and to stretch a net over them and peg it down at the sides. It is not advisable to lay the net on the bushes themselves, as it injures the shoots, interferes with the gathering of the fruit, and the nets themselves are soon destroyed by being pulled about. Cropping between the rows of fruit bushes is not a good practice; let them have the ground to themselves, if they have less of it, and take the vegetables elsewhere. Neither is it advisable do dig the ground much, with either spade or fork, about Gooseberry or Currant bushes; for as the roots are not deep, they are sure to suffer more or less from mutilation. Decayed manure may be forked in a few inches deep, but at other times stirring with a hoe and mulching are all that is necessary. The trees often suffer severely in dry seasons, green fly and honeydew doing much injury; but a good thick mulching of rotten leaves or short Grass will mitigate both greatly if put on in time, and materially help the swelling of the fruit. In any large walled-in garden, a portion of the north wall should be set aside for Gooseberries and Currants. Both do well trained vertically, allowing about 4 in. or rather more between the branches. Indeed, hardly any fruit is more deserving of wall culture; for the trees never fail to bear, while the fruit can be kept till November if netted or matted up. In planting a Gooseberry or Currant wall young vigorous plants should be selected, and it is needless to say that a good soil gives them a vigorous start, and sends them to the top of the wall sooner than they otherwise would be; 2 ft. or 3 ft. between the plants is sufficient, and usually as many branches as are wanted can be originated the first year, and the process of covering the wall goes on rapidly. The leading shoots should not be shortened at all, or at least very little; but all others that grow out from the sides of the shoots should be spurred in to a few eyes every winter. Carrying the leader forward, in fact, and spurring the other shoots is all the training needed. Gooseberries or Currants may be safely planted from October to March if the weather is open.

ROSES.

Planting Roses.—For another month, should open weather prevail, Rose trees may be advantageously planted. The best position is that in which they can enjoy the morning sun until the meridian, and in which, while they have abundance of air, they are protected by evergreen hedges, or other "breaks" and screens surrounding them at some little distance, from the full force of stormy winds. The best soil is a rich mellow loam, into which a walking-stick disappears to the handle, or a strong clay, with a slight element of lime, well dug, and drained, and dunged. If the purchaser wishes to grow the Rose in its highest perfection, he must buy Briers when he buys his Rose trees, and bud the one from the other in the succeeding summer; because, as a rule, the first Rose produced, if it escape frost and the buds around it are removed, will be the most beautiful. In some soils, and in some seasons, many of our best Roses attain their full glory on the Manetti stock; but our indigenous Dog Rose is the most reliable parent of heroes. When the object is to grow Roses for home enjoyment rather than for public competition, I recommend Rose trees on their own roots, or "worked" so low upon the Manetti or Brier that the scion may be planted below the soil, and thus form additional roots of its own.—R. H.

Obituary. — Thomas Tucker, foreman packer for 18 years to Messrs. James Carter & Co., died suddenly the other day, leaving a widow and six children unprovided for. A few friends and fellow-workers have subscribed a fund for temporary purposes, and a committee has been formed to receive subscriptions from

any one desirous of helping the family. Contributions will be thankfully acknowledged by the committee, and should be addressed to it, care of Messrs. J. Carter & Co., High Holborn.

GLASSHOUSES AND FRAMES.

Primula cortusoides amœna for Forcing.—This hardy Primula forms a useful plant for the decoration of the conservatory at this season of the year. Plants of it taken up from the open ground in autumn, and potted and introduced to gentle heat, may be had in bloom from January onwards. They are much more useful for cut bloom than any of the single-flowering Chinese varieties.—S.

The Lemon Grass (Andropogon schænanthus).—This beautiful sweet-scented Grass, with its long, narrow, pale green, wavy leaves, light midrib, and white-powdered stem, is a fine plant for warm greenhouses. When the leaves are rubbed or slightly bruised, they emit an odour like that of the Lemon-scented Verbena (Aloysia citriodora); the leaves are from 3 ft. to 4 ft. long when grown in a 6-in. pot.—R. H.

Triteleia uniflora and Hepaticas in Greenhouses.—How few know the value of Triteleia uniflora for forcing! It is only necesary to bring it into the greenhouse whenever it is wanted, and in a short time it will be in full flower. All the garden Hepaticas open their blooms with the same rapidity if suddenly brought into a warmer temperature. The lilac variety of Triteleia uniflora is a grand plant for a warm border or raised rockwork.—F. M.

Perpetual Carnations.—This is the time to look up the old plants and get them in a little heat, so as to procure some small Grass for cuttings, which should be put in as soon as possible. They will strike as easy as Fuchsias in bottom-heat during February, March, April, and May. Pot off as soon as rooted, and replace in a warm dung bed or pit until well established. Gradually harden off in cool frames until May; then plant out in some open place or keep potting on as the pots get filled with roots, stopping the plants as they may require it. The plants must be lifted from the open ground in September and put in pots, staked, watered well, and placed in a shady place for a few days, then exposed to the sun again; place them under glass before they get saturated with the autumnal rains. When the pots get full of roots, give weak liquid manure once a week. In case the green fly appears, apply Tobacco powder or a solution or Quassia. Do not let any weeds get among them, or mildew will make its appearance; if it does, then apply flowers of sulphur. In the spring plant the old plants against the wall or in a row across the kitchen garden, and strain a few wires across to tie them to, and they will continue to flower the whole of the summer. Strike a fresh lot of plants every year, as old plants are unprofitable in every form. Some leaf-mould, manure, and sand in equal parts, make a good compost for them. With very little trouble, they may be had in flower all the year round in any ordinary greenhouse with a little heat during the winter months. The following are good kinds: White—Avalanche, Vestal, Bride, Flatbush, President Dayren, Ninon de l'Enclos. Scarlet—Boule de Feu, Covent Garden, Dragon, Henshaw, Hubert, Zebra, Jean Bart, Vulcan. Yellow—Ascot Yellow, Prince of Orange. Striped—Ainé, Gloire de Lyon, Miniature, Defiance.—W. H.

Striking Cuttings in Sand and Water.—This, although an old system, is yet a very useful one when properly carried out. No doubt a manure bed under a frame is preferable, but such beds are not always at hand. I have many times found the sand-and-water system useful during the early spring months. I generally employ flower-pot saucers for the purpose, as they are handy to move about. As regards the sort of sand, either silver or drift answers the purpose, and no more sand should be put in the saucer than will keep the cuttings from falling over. The base of each cutting should pass through the sand and rest on the saucer. After the cuttings are put in cover the sand with rain-water of the same emperature as that of the atmosphere of the house, to the depth of ¼ in.; then place the saucers as near the glass as possible and free from shade. Every other day or so drain off the water from the saucers, steadying the cuttings with the other hand, and fill up again; water as before. Thus treated, the cuttings are not so liable to damp off, as they otherwise would be, and the roots are more healthy. As soon as roots appear, take some cow manure or clay and mix it with water to the consistency of thin paint, put it into rapid motion with the hand, and fill up the saucers with this liquid, which will soon saturate the sand and give vigour to the plants. Allow the sand to become almost dry previous to potting, when each cutting will lift out with quite a mat of sand and fibre attached to it. Pots should be ready to receive them, and they should be placed on the soil, sprinkling some of it loosely over them and avoiding all pressure by means of the fingers; place them together on the floor or on a hand-barrow, and give them a good watering through a fine-rosed pot, which will wash the soil down among the roots without damaging a single fibre. Treated in this way, not a single plant need be lost.—J. S. W.

Cockscombs.—Most people admire these, but few grow them really well. They, however, are by no means difficult to grow if a little heat and plenty of moisture can be afforded them. The seeds should be sown in April in well-drained pots filled with rich soil to within an inch of their rims; scatter the seeds evenly and thinly, and cover lightly with a little sand and fine soil. They will germinate best in a frame in a temperature of 65° by night and 75° by day. As soon as the plants appear they should be kept as near the glass as possible, and as soon as they are large enough to handle they should be potted singly in 2½-in. or 3-in. pots. In potting, place them in the soil up to the seed leaves, and in order to preserve the roots from injury they should be carefully lifted. They should be encouraged to grow as fast as possible, and not have too much water; for keeping them dry rather than wet will induce them to produce combs; and, as soon as those that are well shaped can be selected, the plants should be potted into 4-in. or 5-in. pots, giving them a little water a few hours previously. The best soil for Cockscombs is a rich loam, rather inclined to be light, pulled to pieces with the hand, not sifted; to three-fourths of loam add one-fourth of well-rotted cow manure, or the same quantity of rotten hotbed manure or leaf soil and a good sprinkling of sharp sand, mixing the whole well together. In potting, the soil should be pressed rather firmly about the roots, but not so as to make it too solid, otherwise the water will not pass freely away. After potting they must be kept as near the glass as possible, and if they be plunged up to the rim in a hotbed it would be the best position that could be afforded them. The final shift should be into 5-in. or 6-in. pots, according to the health and strength of the plants. There are several forms of the Cockscomb, all of which are worth growing, and the one we now figure, which is being offered by Messrs. Webb & Sons, will doubtless please many who like variety. The comb which is crested breaks into a variety of colours which render it very interesting.

Variegated Crested Cockscomb (Celosia cristata variegata).

MY NEIGHBOUR'S GARDEN.*

IT is a liberal two miles' walk before I can reach my neighbour's garden, but what a charming two miles it is! It is August, very warm, and not a cloud visible; I have a steep hill to climb and when I arrive at the top of it I am half way. To that point I pursue a narrow lane very fairly shaded; after that, an open heath with the heated atmosphere quivering and bubbling like boiling water; it is almost literally so, for the heat is apparently drawing what little moisture there is in the sand and gravel entirely out of them. Nevertheless, the crimson patches of Heather and tufts of Fern seem greatly pleased with it. The heath is in full flower, and innumerable bees are making good use of their time. At the further extremity the ground descends again rather abruptly to a grand extent of level country, and on the horizon that thin blue line is the sea. In the distance on my left I see long dark lines; these are the Fir plantations in the New Forest, a beauty at this distance, but gloomy and tiresome to be among them, and in some places a great disfigurement to the landscape. I should like to know why a little landscape gardening could not have been exercised? one of the rules of that art being variety and contrast of foliage. I cannot say whether it is imagination on my part, as I have never verified the matter, but it has always struck me that the New Forest and for some distance about it is an unusually high temperature for England; when in it I have always found the heat very great. It would be worth while making some registers in a central position; if it is so, the cause would be most likely the gravelly surface soil and the absence of water.

I believe I am so far correct in believing that arid soils generate heat; one ought not to be

* Sequel to My Cottage Garden (page 509).

too near them, but if such is the case it is one of the causes why my neighbour's garden is so complete a success. He is as close as possible to a large extent of arid surface. I therefore please myself with the idea that I have discovered one of the items of that success, but the soil of that garden, though sandy, is very unlike that of the heath above mentioned. I have not expressed that view of it to him, because his own opinion is, the effect is chiefly due to energy and cartloads of stable manure. We have now crossed the heath, and the ground descends, and there stands the lodge and entrance; from that the road to the house is carried artfully to the right, so the descent is scarcely perceptible; the house itself is on level ground, but it required a good deal of terrace-work, and from this terrace you may still descend to the fields and valley in the distance.

The house is a tasteful specimen of a villa, red brick with white stone facings, and possesses every comfort and convenience. You cannot help exclaiming, What a situation for a house! You have from the terrace a view as extensive and varied as it is possible to have; in front, to the right and left, green meadows, a distant river shining here and there, cornfields, woods, hamlets, as far as the eye can distinguish them till lost in the blue distant horizon. The glories of an English landscape are never so perfect as in August.

The garden, or vegetable garden, is to the left, and commences very nearly at the brow of the descent before mentioned, and I do not remember ever seeing a garden so boldly placed on an incline; it is indeed on the steepest part of the hill, and receives the light from sunrise to sunset. Many would have hesitated about it, and many positively afraid. One's idea generally of a garden is a flat surface, and thus they are usually formed. Though not quite so steep as a railway embankment, my neighbour's garden put sone strangely in mind of one; it is not at an angle much less. If any one had to debate with himself beforehand, he would come to the conclusion that esculents could never succeed under such aspects, for they would be burnt or stunted from want of water; that the gardener's strength would be unequal to so much up and down hill. But there is no complaint on that score; and for the former a spring was known to be near the upper end, which has been led into tanks, so that the ground can at any time be thoroughly wetted with a hose. The vegetables were all in fine condition, even to the late Peas, one of Laxton's late varieties, the Onions, silver-skins, and very large. The garden is walled all round and the walls are covered with some composition laid very smooth, so that insects cannot harbour, and the fruit trees, chiefly Pears and Plums, fastened to wires strained horizontally. I groaned in the spirit to think of my old brick walls at home, honeycombed with years of hammering in nails and shreds, the nursery of every conceivable pest, and where even the Red Currant trees have declined growing, and thought how slight the knowledge of these matters was to our grandfathers and grandmothers, and how little they heeded such trifles. There was very little fruit on these trees, partly on account of the last severe spring, and partly from their being lately planted. At the north or upper end of the garden are two glasshouses, very lofty and freely ventilated, or rather they may be called one, except that the doorway being in the centre divides them, but they go the whole extent of the wall. On one side were Tomatoes, Vick's Criterion, Mammoth, and the Grape or small kind, used for bottling and preserving. They were beginning to ripen, and hung in beautiful clusters; the shoots extended quite up to the roof, so that the wall appeared one mass of leafage. I observed to the gardener that I perceived he did not cut them nor remove side shoots; he merely replied that he "wanted fruit," by which answer I concluded he only wished for quantity, not quality. I still think they would have been better had some of the side shoots been removed. The other side had Nectarines, and in front of them close to the lower ventilators Plums (Coe's Golden Drop) trained inwards upon wires. On one side of these houses, towards the east fortunately, an old coppice existed which has been left so that the trees are close above the wall, and afford great shelter. In front of these houses are Melon frames and propagating frames with heat below; they are quite central and fully exposed, but shaded occasionally.

The greatest attention is centred in the Peach house, it is very long and high, but no great width. There are several varieties, early and late; quantities of them have been gathered and sent to market and the gardener was then dispatching eight dozen. How my parched mouth watered. How speedily it was relieved by that estimable gardener. Never was anything more grateful. Nothing else is allowed to grow in this house, but a few Peach trees are trained as before, their stems close to the wall, and the branches trained inwards and upwards, but they did not appear to me to be very successful; nothing equal to those on the wall.

The Vine house is equally cared for; there are only two kinds, Black Hamburgh and Sweetwater, both laden with huge ripe bunches. I looked closely for mildew, but not a trace could be found, nor an eye-offending spot; it would be next to impossible in such a situation and pure air. The gardener was kind enough to point out the rods he intended to remove, and the eyes from which the new rods would spring; not in every case the lower one.

Now in all these houses no heat is ever used except in the Vinery, and that is not on account of the Vines, but merely to force Asparagus in the borders, and is put on about this time at the end of the year. My neighbour has relied entirely upon pure fresh air and uninterrupted light, and the result is luxuriance and abundance. Five years ago the place was nothing but small enclosed patches, misshapen hedges, and sandbanks; all is now order and beauty.

Besides these there is a fine row of dwarf Apple trees, but they were sadly used last winter with the exception of one, a Golden Reinette; they are, however, very recently planted, or rather transplanted. They will be treated in the way now, I believe, considered the best—moved every third or fourth year, pruned back and root pruned; but I sometimes doubt whether we shall leave full bearing trees to the next comers by this system. At the present moment I prefer my own venerable sires, "green with Moss and grey with Lichens," 15 ft. or 20 ft. high, wide branching and Mistletoe hanging about, for they have never failed in cropping for five and twenty years. W. T.

TOWN GARDENING.

WINDOW GARDENING.

EVERYONE has not a garden, and but few can indulge in the luxury of a greenhouse, but every one has at least a window or two that can be utilised for growing flowers, either inside or outside or both, and what can be prettier than a window full of well grown plants? On the window-sill outside, in pots or a box, or in the room itself, many things may be successfully cultivated in any town, however large and smoky; and we will now show what plants are most suitable for such places, and the best mode of bringing them to the highest state of perfection. But we must again here call attention to the remarks given at the beginning of these articles about attention to cleanliness, &c.; these are even of more importance here than as applying to outdoor gardening, for plants in pots and small boxes are far more difficult to keep in health, and far more easily injured by even slight neglect, than those in beds out-of-doors. So that constant, unvarying attention and care are indispensable to the satisfactory culture of plants in windows; more so, indeed, than in any other situation.

There is no excuse either for any neglect of the plants, for a window, or even three or four windows, hold comparatively so few, that it is easy to attend to them as they should be attended to; while, where greenhouses are employed, and many hundreds, or perhaps thousands, of pot plants grown, it is excusable for some to get overlooked or neglected sometimes. Remember that a day's or even an hour's neglect in critical periods will often undo and spoil the results of months of previous watching and care.

In window gardening there are some things that must always be kept inside; some that, protected from the cold of winter by being placed inside, may be exposed to the open air with advantage in summer; and some again that will stand the exposure outside both in winter and summer, but there are very few of these last. If plants are grown inside the window, it is absolutely necessary that there be no gas burned, not only in the room itself, but in any part of the house, except, perhaps a very distant portion. Even in the sweet country air, gas sadly injures anything that comes in contact with its fumes, but here, where everything is against them, it is certain death to almost every kind of plant if exposed to its influence for any length of time. Even where no gas is used it will be found difficult to get more than a very few plants to flourish and look healthy in an ordinary living or sitting-room. The air, always dry and harsh in towns, is still more so in a room where a fire is often burning; the air is often close, for if the window is much open the "blacks" come in so badly. Always dusty, the air is still fuller of particles where people are always moving about. All these things are against the plants, but do not despair. Study their wants and requirements, do the best you can for them, and you are sure to succeed with something. The best place is a room not very much used, where the air is still and not so very dry. The window should look south or in a southerly direction to suit most flowering plants, but an east or west aspect will do for most things almost as well; and Ferns, even some greenhouse Ferns, will flourish as well in an east, west, or north aspect as in a more sunny position, perhaps better.

All plants should be kept as close as possible to the light, that is, to the glass, and by no means crowd them together. Four or five good sized plants are quite enough for an ordinary moderate sized sash window, unless you have a proper stand, and another rank behind the first. Unless used to gardening operations, do not try a lot of delicate things at first, at least, though you may be fond of them; far better have only good hardy plants, such as Geraniums and Fuchsias, until you have got the knack of managing them, when you may, if you like, go in for something more ambitious. Lists of the most suitable plants are given a little farther on. The main thing after the plants are once established is to keep them clean. In summer when it rains gently place your plants out-of-doors to get their leaves washed and enjoy the beneficial effects of a shower; and in winter take them into the back kitchen or yard or other suitable place, and syringe them or shower them overhead well with a fine-rosed watering-pot, or even a good sprinkle with a brush will do in default of anyting better, using clean water at a temperature of 65° or 70°, or tepid. If you can get it, always use soft water for plants, both at the root or otherwise, in preference to any other.

All plants should be potted in good fresh soil at least once a year, and the material used should be of the very best description. Full directions regarding composts, &c., have been given. A bushel of good potting mould can be purchased at any nurseryman's for 1s.; this will fill a good many pots, and will be a shilling well laid out; be sure and tell the man what kind of plants you want it for. About the best mixture for the ordinary run of window plants is three parts of good fibrous loam, and one part each of leaf-soil and well decayed manure, with a good sprinkling of silver sand and a little crushed charcoal to keep it sweet.

The best plants for cultivating inside windows are—

*Amaryllis purpurea (Vallota or Scarborough Lily).
*Aspidistra lurida.
*Begonias.
*Calceolarias (shrubby).
*Calla (or Arum) Lily.
*Campanulas.
Cannas.
*Ficus elastica (India-rubber plant).
Ficus Parcelli.
Fuchsias.
*Geraniums (Zonal).
Hyacinths.
*Lobelias.
Mignonette.
*Mimulus (Monkey Flower).
*Musk.
*Pelargoniums (show and fancy).
Primula verticillata.
*Petunias.
*Spirea japonica.
Tulips.

The above are suitable for very thickly inhabited and smoky parts, but in such districts as Brixton, Kensington, Camden Town, Hoxton, Bow, &c., or anywhere but in the heart of a large town, the above list may be augmented by the following:—

Azaleas.
*Abutilons.
*Balsams.
Bouvardias.
Camellias.
Coronillas.

Cyclamen.	Nierembergias (for hanging baskets).
Deutzias.	Primulas (Chinese).
Dracænas, congesta and Cooperi.	Roses, China and the Fairy Rose best.
Ficus Cooperi.	Smilax.
Genistas.	The Sensitive Plant (Mimosa pudica).
Heliotropes.	Thunbergias.
Liliums, of sorts.	
Myrtles.	

The most easily cultivated are marked (*). It is not much use trying to raise plants from cuttings where there is only a room and window available, excepting, perhaps, Geraniums, which will strike anywhere in July and August; or unless you have a bell-glass or two, under which you may root almost anything. Put the cuttings thickly in small pots, using sandy soil, and cover with the bell-glass, only removing it for half an hour morning and evening, and shading from bright sun; pot off when rooted. It is much better on the whole to buy a few healthy young plants and keep them as long as possible; they only cost a few pence each. But we would warn our readers against buying pot plants from the trucks in the streets, as a rule, unless you only want a temporary display. There are exceptions, of course, but in most cases these plants have been raised in a healthy country place; they are young plants grown rapidly in heat and forced early into bloom, so that they have no constitutions, and when removed into the dry and ungenial air of a town room or window speedily droop and die. Their fresh and delicate beauty is often a direct evidence of their want of strength, and the only way to save them is to place them in a greenhouse or conservatory, or even in a window case or frame, in which they may find something approaching the atmospheric conditions in which they were grown, and then to harden and gradually inure them to their new and less genial surroundings. Fuchsias especially are very often grievously disappointing when purchased in this way; at the best there are only comparatively few kinds that can be successfully grown in towns, and when naturally delicate varieties are subjected to the severe check described, the opening buds speedily drop off and the plants lose all their beauty if they do not die outright. But though it is not easy to raise cuttings, seeds of many things may be sown and successfully grown into good plants. A few suitable for this purpose are Lobelias, Petunias, Mignonette, &c. Full directions for sowing seeds have already been given.

For sunny windows have Geraniums, Pelargoniums, Lobelias, and other sun-loving plants; but if shady, Ferns, Fuchsias, Begonias, and such things would do better, and a hanging pot or two of Campanula grandiflora, Creeping Jenny, or Lobelia is always effective.

ANSWERS TO QUERIES.

4024.—Sowing Tulip Seed.—The time for sowing will be about January or February. Sow in good sized pots, and when you sow seeds do not put them flat in the earth, but put them in sideways. With care, in a few years they will flower, and be what are termed breeders. The breaking of these breeders will be a very pleasant and exciting employment, and you will stand a chance of now and then getting a gem of the first water which I hope will be the result. As to soil, they grow in nothing so well as in plain good sandy loam, taken from a pasture with the turf rotted in it.—H. ROBERTS.

Sowing Seeds in Windows. — Can I now sow the following seeds in my window with any chance of success—Lobelia magnifica, Papaver Rheas, and Convolvulus unicaulis? [Yes; but you had better wait another month or so. Sow in pans or pots of sandy soil well drained, and cover with a sheet of glass.]

Clay's Fertiliser.—*M. T.*—Mix a 4-in. pot full with say half a bushel of soil, and use it as a top-dressing to your Camellias, &c. It may be applied two or three times during the year if necessary for the plants.

Lingden Hazel.—See page 532.

J. L. C.—Messrs. Barr & Sugden, 12, King Street, Covent Garden.

Names of Plants.—*W. B. H.*—1, Cattleya Harrisoni; 2, Centropogon Lucyanus; 3, Eupatorium Fraseri; 4, Sedum carneum variegatum.——*Nemo.*—Begonia Waltoniensis.

QUERIES.

4081.—Spiræas Decaying.—I have several plants of Spiræa japonica, and I find that they are rotting away. I have taken them out of the soil and washed them, leaving them in water, and have repotted them, and I still find that they are going. Will anything stop the decay?—AMATEUR.

4082.—How to Propagate the Mistletoe.—Will some one who has succeeded in growing Mistletoe on trees from the seed, kindly give the needful directions? It grows freely in this neighbourhood on the Apple and Lime, and is found on the White Thorn.—D. C. F.

4083.—Culture of Eranthemum pulchellum.—I find these plants so valuable for affording a supply of cut bloom of a very beautiful blue colour, that I should be glad of some hints on their culture and propagation. What soil is most suitable for them?—HORTUS.

4084.—Azalea mollis After Forcing.—An article on the treatment of Azalea sinensis and mollis after forcing would be very acceptable to many readers who, like myself, have commenced to force these plants. Can plants forced this season be grown on and forced next and succeeding years like A. indica?—HORTUS.

4085.—The Onion Plant not Flowering.—Will some one tell me the reason of Onion plants not flowering? I have had them for months in a greenhouse; they keep growing, but show no signs of flower.—CLAPTON.

4086.—Grafting Fruit Trees.—I am thinking of planting some stocks for grafting some Apples and Pears in the spring. Would it be too late to put in the stocks now to graft in the spring? or must I wait till autumn? I have been advised to plant the Paradise stock for the better kinds, but, being an amateur, I do not understand the meaning of the Paradise stock. If any reader would give me some information I should be greatly obliged; also the difference in the Dutch and English Paradise stock and the free stock.—A CONSTANT READER.

4087.—How to Grow Cucumbers.—Will some one tell me how to grow Cucumbers? and can I grow French Beans in pots in the same house? My greenhouse has a wall at the back and one end, but it gets all the sun.—T. BOX.

4088.—Humea elegans.—I wish some one would give some hints as to the proper cultivation of this graceful plant. The stalks of mine have all turned brown. They were each potted out into a mixture of good soil and silver sand in 5-in. pots and grown in conservatory heated with hot water.—M. J.

4089.—Laying Down a Lawn.—I have a large plot of Grass which I want to convert into a tennis court, but at present it is on a slight incline, and growing coarse Grass. Will some reader say the best way of levelling it? Will it do to fill up with good mould well rolled and sow good Grass seeds? Is there any fear of the old Grass springing up through the mould which in some places will not be more than 2 in. deep? and if so, will it form a good sod by the summer?—A. H.

4090.—Erecting a Cucumber House.—I am desirous of erecting a span-roofed house about 9 ft. long by 7 ft. wide in which to grow Cucumbers, Cockscombs, and a few other flowers. I propose to heat it by means of a brick flue. Will some reader give me his experience of such a place as regards height of walls and roof? also the best means of ventilation? also the best way to have it situated, as it will not be attached to any other building? also some little advice as regards the interior and making of the beds for the Cucumbers?—YOUNG GARDENER.

4091.—Growing Mushrooms.—I have a wooden shed about 12 ft. square placed against the kitchen (stone) wall just where the fireplace is. The heat of the fire is easily felt by the hand on the wall over a space of about 4 ft. square. My idea is to place four or five shelves against this part of the wall and to curtain them round with brown paper, matting, or old carpet, so as to prevent the heat escaping; then to place on them fresh stable manure and Mushroom spawn as directed in GARDENING ILLUSTRATED of December 11. Would fowls' manure (in which I believe there is a great deal of heat) mixed with earth, perhaps, do instead of stable manure? I shall be glad of any suggestions.—H. W. B.

4092.—Christmas Roses from Seed.—Will some one having been successful in cultivating Christmas Roses kindly inform me how, when, and where is the best place and time to sow the seed with a few hints as to after management till large enough to plant out?—CHRISTMAS ROSE.

4093.—Covering Hot-water Pipes.—Will some one kindly inform me how to cover some hot-water pipes which run through a building in which heat is not desired? I thought of boxing them up with boards. Would it be safe, as the boards would have to nearly touch the pipes?—CIRCULATION.

4094.—Sowing Fern Seeds.—I find in the spring seed lists "Fern" seed quoted—common, greenhouse, and stove. Will some one inform me the best means of vegetating and growing them?—FERN LEAF.

4095.—Early Potatoes for Damp Soils.—I want two bushels of Potatoes, and should be glad to know what sort would best suit for my purposes for planting. The soil is good; it was well dug over in the autumn after a crop of Cabbage, but it lies low and damp, consequently the frost generally cuts it till late in the spring, which prevents my planting so early as I otherwise should do, and as I wish to plant that part of my garden with Potatoes for sale in the spring, I would like to know what sort of Potatoes would come to perfection in the shortest time? As the weather was favourable last spring I had a beautiful crop of early Almas, which I sold at 10s. per cwt. I have a good cellar where I could put the Potatoes on boards or in boxes, so as to get strong sprouts on ready for planting.—THE MARSH.

4096.—Celery Fly.—Will some one explain the cause of Celery fly and the means by which it may be prevented?—BETA

4097.—Worms in Conservatory Border.—Can any one tell me how to get rid of worms in a border in a conservatory? they come out at night and tear the Lycopodiums sadly.—E. S.

4098.—Books on Botany.—I should feel obliged to any correspondent of GARDENING who will furnish me with the names of any small books suited to excite in children a taste for botany.—MISS V.

4099.—Hyacinths in Glasses.—I have a fine Hyacinth bulb in water; the roots are half-way down the glass, and seem strong enough, but lately they have become brown at the ends, and their growth seems arrested. I think the spike is going to be very small in consequence. What should I do?—M. C. K.

4100.—Manuring and Planting Fruit Trees.—Will some one kindly give reply to the following? I have a small garden devoted to fruit and flowers. The soil is rather a heavy loam. What artificial manure, solid and liquid, can be recommended, from experience, for general purposes, upon such soil mentioned? and how and when should they be applied? I have neither room nor inclination to store a heap of dung or leaves to rot into manure. When and with what is best to manure Gooseberries and Currants? Are soap-suds and house-slops useful? and should they be used diluted? I wish to grow some fruit trees against a wood fence having a south aspect. There are at present several Chestnut and Oak trees about 15 ft. high in the border of this fence. Must these trees be removed to render the border fit for the fruit trees? and what fruits will be most suited to this position? I am about 10 miles south-east of London.—CLARION.

4101.—Amarantus caudatus.—Some years ago in Florence, in the little garden of the Piazzo Santo Spirito, I saw some very remarkable specimens of the Amarantus caudatus or Love-lies-bleeding. They had a bare, hard, woody stem, about 5 ft. high, above which was a flat, spreading head some 3 ft. in diameter, bearing great crimson racemes of flowers, 1 ft. and more in length. They were planted in a circle near the centre of the garden, and formed a very grand effect. Can any one tell me how they could have been grown? I thought it probable they had been treated in a similar way to the Tree Mignonette. It would be an experiment well worth trying by one who has space and time for it.—W. D.

4102.—Transplanting Pear Trees, &c.—I have some Pear and Apple trees about twenty years old, and some large standard Roses standing on ground now required for buildings. I should be glad to save them, the former especially. The subsoil of their intended site is brick earth; the surface soil about 2 ft. deep is a good stiff loam in good condition. How deep should I make the holes? how provide for drainage? and with what compost would it be best to fill in the holes? I have plenty of turf, turfy loam, and old hotbed manure. Should the trees be cut back?—M. M.

4103.—Plants for Greenhouse.—I have just built a glasshouse at the end of my dwelling, N. E. aspect, and opening out of my drawing-room by casement doors. I want to fit it up with creeping and hanging plants that will thrive well with such attention as a lady can give independent of a gardener. I thought the two ends of the glasshouse might have cork fitted on to them, and Ferns growing in it, but I do not know how to proceed. I ought to say that I wish to keep the floor as clear as possible. I have a stove fitted which will be used in cold weather. The house with lean-to roof is nearly 16 ft. high and 16 ft. long.—F. E. G.

4104.—Salt as a Fertiliser.—I have a garden of bush fruit (Gooseberries, Currants, and Raspberries) and I wish to dress it with salt to act as manure, and also to kill insects, with which it is infested. Please say the largest quantity I can use with greatest benefit on every 8 square yds. (or space of 8 ft. by 9 ft.).—J. T. W.

4105.—Propagating Mulberry Trees.—Can any reader inform me how to propagate the Mulberry tree from seed or from cuttings, and where I could procure them, as I am going to North America? and I should like to take a few specimens with me for a particular purpose? If any one could tell me of a mode of packing a few cuttings, so as they would take root when I get over there, which will be about the beginning of March, they will greatly oblige.—AN EMIGRANT.

4106.—Insects on Plants.—Would paraffin used, one wineglassful to four gallons of water, kill green fly and not injure the plant? I read somewhere of Castile soap being effectual; could any one say what strength to use it without hurting plants? I want to dress Rose trees, &c., in greenhouse.—ONE IN TROUBLE.

4107.—Lilacs in South Africa.—I have just succeeded in introducing the Lilac here. I shall be glad if any one will inform me how to cause it to bloom in pots, and if it would die after flowering.—W. ADAMS.

4108.—Planting Mistletoe.—What is the best time for planting the seeds of Mistletoe in the bark of Thorn or Apple trees?—W. D.

4109.—Begonias for Bedding.—Should tuberous-rooted Begonias intended for bedding out be started into growth in a hot-bed? and when?—W. D.

4110.—Propagating Begonias.—What is best way of propagating tuberous-rooted Begonias (not by seed)? Can it be done safely by dividing tubers? When is best time for taking cuttings and treatment of cuttings?—HEATH END.

4111.—Double Geraniums not Flowering.—How can I get a double Geranium to flower? I have a very strong pink one, and each year it is full of leaf, but very little flower. Last spring I divided it and took all the slips off, and now it has a lot more (and leaves too), although it has been in a cold room all the winter, and there has only been a fire two or three times. It is in a large pot, but I could not get the roots into a smaller one. It is provoking to see it so strong, and have no flowers, for any there may be die off so soon; it was in the garden all the summer.—BEE.

4112.—Pea Oxford Tom.—Where can I get that good old Pea, as I do not see it in any catalogues now?—NESS POINT.

BEES.

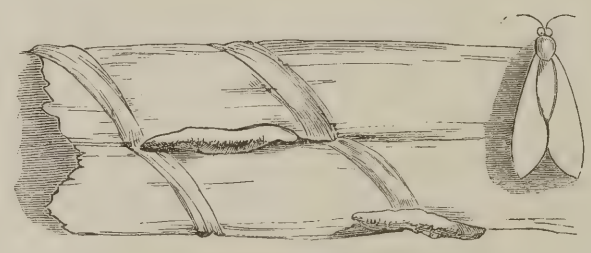
THE WAX MOTH.

(TINEA MELLONELLA.)

MANY persons, even in the country, who keep bees are quite oblivious as to the cause of their continuously loosing stocks one after the other. They turn up a hive, suddenly found empty, and find a quantity of maggots inside, never imagining a little insignificant moth has succeeded in laying its eggs inside and driven the bees entirely out of their home. The author of the "Bee Keeper's Manual" speaks of this insect, and it is to be regretted he had not experienced its ravages, or he certainly would have given more information, and perhaps found some remedy. The writer of this article constantly visited hives and saw his methods ; he also assured him he had never seen any wax moths about his hives.

In some places they are too abundant to be pleasant, as and for many years I have invariably lost one or two stocks from wax moths.

As far as it is possible for me, I can suggest one or two matters that will prove useful, and it is as well that so important a subject to those who keep bees should be constantly ventilated. so that possibly some one may find some method whereby the bees may be thoroughly protected. The male of this moth is about ½ in. in length, the female rather small, but far more active ; she is rarely seen before June and is not absolutely dangerous till later, the reason being the bees are continually clustering at the mouth of the hive, or swarming, at which time the moth knows it is useless to attempt to enter. They are both cream colour or rather whitey-brown all over, the under parts shining like silver. They are extremely delicate ; so much so, that if taken and crushed with the finger and thumb, no perceptible substance can be felt. When the bees commence their steady work after swarming is the time when they may be seen about the hives. Their flight is very short, but they run or glide with great rapidity, generally making for the mouth of the hive, getting as near to it as the bees will allow. Now and then a bee will make a dart at the enemy, which they avoid by a motion of great rapidity. Now, if one of these moths obtain entrance, the doom of the hive is certain ; they begin at once to deposit their eggs, and by autumn the bees will have deserted the hive.



The Wax Moth (Tinea melonella).

It is quite evident that the moths at such time were not reared in that hive ; they were either produced in some ruined hive which has been allowed to remain open, or the cocoon containing the grub was deposited somewhere about the hive—sometimes underneath the floor board, oftener deposited between the straw bands, as in the illustration. When the moth obtains a footing inside, the eggs are deposited in the same place, from whence the minute grubs work to the comb which they soon destroy, and when they form their cocoons they take up the same kind of position inside ; a favourite place for them is round the bottom of the hive. I have seen the lower edge inside with a complete row of them all round ; in this state they are difficult to detect, as they become covered with small particles of wax or propolis.

At the end of summer, then, every hive should be carefully examined all round the stitches and bands, and any cocoons extracted with the point of a knife ; the floor board also should be well brushed underneath, and powdered with Tobacco powder, and any place outside at the bottom where they could find entrance stopped. A good plan is a band of calico soaked in clay puddle and strained tightly all round. In straw hives on the depriving system the hole at the top must be examined, and the cork well fitted, as the smallest crack is sufficient for the grub to enter ; for when the moth is unable to do so the eggs are deposited in all places where there is a chance of admission to the grub.

As a general rule, strong stocks are safe, as the population enables a numerous guard to be always at the entrance. Weak stocks, on the contrary, are those most certain to be invaded. Whenever the bee keeper has leisure, he should examine his hives towards evening in summer, and destroy any moth he may discover. It is certainly difficult to catch them, as when still they are hardly visible on straw, which is so nearly the colour of the moth.

If it should be found that a hive is suffering from the moth, no time should be lost in driving into another hive ; and if a stock is hopelessly lost, smoke the hive to prevent any moths escaping, carry it away and burn the entire comb, scrub the inside well, when it may be used again if thoroughly clean ; but I have been assured, by a person who kept bees for many years, that it is not safe to use for two or three years after. That may be just possible, but I have successfully hived bees in well cleansed hives that had suffered from wax moth the year following, but in the case of old hives, it is best to burn the whole at once. W. T.

Dorset.

POULTRY.

Heat for Hatching Chickens.—On p. 530 of GARDENING, under the head of "Heat for hatching eggs," I note there is a disparity of opinion. As I have had a great deal of experience with hydro-incubators, I may state that the difference in all probability arises from the fact of the temperature being taken at different levels. If a carefully registered thermometer is placed on a level with the top of the eggs in the egg-drawer, the correct heat for hatching is 104°. At this level an egg will not incubate below 98°, and it stands a great chance of being spoilt if the thermometer rises for any length of time and stands at 108°. For the first ten days eggs do not require much change of temperature, and they can endure more heat. At that period the lungs of the chicks begin to work, and a supply of fresh air is required through the shell. It has lately been found out that by placing quicklime in the drawer of the incubator that the air is greatly purified and the chicks come to maturity much stronger and healthier. People who had worked most carefully with the incubator failed to obtain a good per-centage of live chicks. After employing the lime in the drawer they hatched strong, healthy chicks out of every fertile egg. Mr. Lemoine in his work upon incubation states that he invariably changes the nest under each hen three times during the twenty-one days and places sulphur under the straw. To such a pitch of perfection has he carried it, that if he finds the hens are not giving off sufficient warmth (in his opinion), he crams them, and so forces them to take more nourishment.—T. CHRISTY, *Malvern House, Sydenham.*

BLACK HAMBURGHS IN SMALL SPACES.

IT is with much interest I have read in GARDENING the notes on prolific poultry, poultry for small spaces, &c., and now that the year 1880 has closed, I will as briefly as possible give details of the few I have kept for twelve months. Four hens and one cock I had from January to third week in March ; then I bought two more pullets, one of which got hurt in the beginning of September, and I thought it best to kill it, leaving five and a male bird, which makes an average for the twelve months of rather over five hens kept besides the male bird ; these were black Hamburghs, and have been closely confined in two pigsties covered with netting, making a run of the two yards each 6 ft. square. I put light doors to the two inner places with a square hole cut out of front bottom corner for an entrance. One of these places they roost in, the other has four wire cases half full of sifted ashes in which they lay, as I find it does not harbour insects as hay or straw does. The floors of the inner places are also covered with ashes, so that in cold weather they always stand warm, and in hot weather it keeps down insect life. Every week all through the summer I sprinkle quicklime in the boxes and about the roosting place, now and then putting a little flowers of sulphur among the ashes in the boxes, and the outer places well washed out nearly every week, and the fowls have always been in splendid plumage, and not any one of them has wanted to sit since I have had them. Their food for first morning meal consists of the Potato parings from the previous day, boiled, and when done all the water well drained away, then mashed while hot and mixed with sharps to a consistency almost dry and quite crumbly ; this they have warm, and their second meal consists of Barley one week, and Indian Corn the next. They have all scraps from the house and bones to pick, and when I can get it, a bit of horseflesh which is boiled and cut up small, the Grass off lawn, and Cabbage leaves, and a shovel full of lime riddlings I occasionally throw into their place. The undernoted statistics may be useful to amateurs like myself. Every evening I have put down what eggs come in in the day, and each week put down cost of food.

1880.	Eggs from 4 hens.	Average eggs per hen.
January.	19 ,, ,,	5 minus 1
February.	42 ,, ,,	10 and 4 over
March.	94 { 42 from 4 hens to 15th. / 52 from 6 hens to 31st.	{ 10 and 2 over / 9 minus 2
April.	104 from 6 hens.	17 and 2 over
May.	144 ,, ,,	24
June.	134 ,, ,,	22 and 2 over
July.	129 ,, ,,	21 and 3 over
August.	120 ,, ,,	20
September.	82 from 5 hens.	16 and 2 over
October.	24 ,, ,,	5 minus 1
November.	11 ,, ,,	2 and 1 over
December.	36 ,, ,,	7 and 1 over
Total.	939	

I have paid out of pocket for keep for the twelve months £1 9s. 9d. ; and price of eggs here has never been less than 1d. each, and for some time 2d. ; we have never had to buy, and have given many away, and also sold some. Not having had the same number of hens all through the year it is somewhat difficult to get a correct account of the number of eggs per hen per annum, but as near as it will come is about 175. I think it very fair for a commencement in keeping a few fowls.

HOME PETS.

Changing the Colour of Canaries.—In answer to "Mervyn," cayenne pepper does change the colour of canaries by bringing them from yellow to orange. As to injuring them, opinions differ, some holding that it does others to the contrary ; probably sufficient time has not been given for experiment and close observation. I know the canaries like the pepper and eat it greedily, but "Mervyn" must understand it is only effective while the birds are moulting ; it does not at all interfere with their song. However, if he likes to try it the following is my recipe : Boil an egg very hard and then chop it up, shell and all, very fine. Pound in a mortar two or three sweetish biscuits, then put in a large teaspoonful of pepper (best Natal), mix with a knife to crumbly state. It will keep fresh two or three days. It will be necessary to give the birds a little canary seed at the same time.—JOHN PEARSON.

Insects in Birds.—In reply to "Myra" and "Beta," also for the benefit of any reader who keeps birds, speaking from experience, I may say that Keating's insect powder is very effectual and thoroughly harmless to birds of all kinds. Some time since I bought a lark at a bird shop ; when I got home, to my disgust, I found it "alive" with insects. I immediately shook a lot of Keating's powder under the wings and worked it well into all parts of its body. I repeated the dose twice afterwards, and had then completely rid my bird of these pests. If the cage is much infested, I would advise washing it thoroughly with strong saltpetre water very hot, sprinkle the bird with powder, and use some powder about the cage and in the sand for some two or three weeks.—FERNDALE.

Treatment of Love Birds.—How should these be fed ? and with what food ? Do they require green food ? Any information as regards their treatment and management will be thankfully received.—J. J.

Canaries.—My canary has a wen on its back, just above the tail, about the size of a canary's egg What is the cause of it, and how am I to cure it ?—MAJOR.

GARDENING

REGISTERED FOR TRANSMISSION ABROAD.

MAGNOLIAS.

MAGNOLIAS, where they succeed, are among the grandest of flowering shrubs or rather small trees. Unfortunately, the evergreen species are not sufficiently hardy to thrive without protection in winter, except in the more southern counties, and even there they make but slow progress as standard trees. M. grandiflora, which we now figure, one of the finest of the whole family, succeeds against a south wall in most parts of the kingdom. In Dorsetshire and Kent are grand trees of it 30 ft. high, and if the wall against which they grow were higher, they seem capable of attaining a height of 50 ft. I have cut from it repeatedly growths 6 ft. long which were overtopping the wall, and, curiously enough, those succulent branches never receive any injury from exposure to frost and north winds; hardiness seems much to depend on the protection given to the roots and boles of the trees. Of all the varieties of Magnolia, M. grandiflora exoniensis is the best; its foliage is of a paler green than that of the species, more regular in shape, the margin recurved, and the under side more thickly covered with a brown tomentum; it is a most prolific flowerer, and continues in bloom from June to October, and even later in favourable seasons. The ordinary M. grandiflora is a more robust plant altogether than exoniensis; it has more shining, Holly-green foliage, which is not so handsomely shaped and broader than that of exoniensis, and it does not flower so freely, but it sometimes ripens its seeds, which exoniensis does not. M. grandiflora may be readily propagated by means of layers, and it will grow in any well-drained soil—a sandy yellow loam seems to suit it perfectly. M. tripetala, a deciduous species, sometimes called the Umbrella Magnolia, makes a very handsome lawn tree; it forms a round-headed specimen, 20 ft. high and 30 ft. in diameter of branches. When old these attain a pendulous habit, the points turning up again like the branches of a candelabrum. The leaves, which are large and handsome, are arranged in whorls round the points of the branches, and, hanging down by their own weight, are not unaptly likened to so many parasols or a huge candelabrum. Suckers from the root of this species made growths in a season 5 ft. long and as thick as one's thumb. The flowers which appear in spring are white and very large, but by no means beautiful, nor do they possess the most agreeable scent. This species seeds freely here, and the seeds, which are like small Coffee berries, are enclosed in a red pulpy coat, which is again enclosed in a pod. Sometimes two seeds are in one pod, and these pods are arranged on a terminal spike something in the form of a cone; the pods open like those of the Furze, and the seeds drop out in November. Seeds of it are obtained in abundance in France. Of Magnolia purpurea, which is a free-flowering deciduous species, the variety called gracilis is the best; it is of twiggy, pendulous habit, and makes a handsome floriferous shrub when grown in a situation which suits it. The flowers, which are pale purple in colour, open in May and June, and last a long time on the tree, or when cut in glasses. I have not seen it ripen seeds. I have many plants of it growing in different situations, and I find that it does not succeed well in dry, exposed localities, or in dry soils. In a shaded, moist position it develops its foliage much more satisfactorily, and every twig is terminated by a handsome pendulous blossom. Our best bush of this Magnolia is associated with some very fine specimens of Rhododendrons, which make foliage more like that of a common Laurel than a Rhododendron. M. glauca is a handsomer plant than the kind last named so far as foliage is concerned; it requires a moist and somewhat shaded position.—E.

MAGNOLIA GRANDIFLORA.

MY GARDENING FAILURES.

For the sake of "Disappointment" and other ignoramuses like myself, I give the experiences of one who has culled what slight knowledge he possesses from experience and Gardening Illustrated.

Three years ago I began gardening with a small greenhouse about 11 ft. by 9 ft. without any means of planting out, the greenhouse being some 12 ft. about the ground and built on a balcony. I have no frames, or means of storing moulds, &c., manures, or manure water, and yet I have contrived to gain a vast deal of amusement and some success with little expense. I see to everything myself in the spare time I get, viz., between breakfast and departure for business and any spare afternoons, &c., I may have. I have a good many Geraniums and other hardy and half hardy plants and shrubs which bloom little in the winter and luxuriously in spring, summer, and autumn, some of which I plant out in the garden in summer to be brought in again when the leaves begin to fall. Climbing over part of the roof of my greenhouse (on string netting, as I have found wire netting most injurious) is a Passion-flower planted in a box covered with Virgin cork, some 2 ft. square or rather cube, which has grown to excess, and was covered with magnificent blue and white blossoms this autumn; the other part of the roof has a Lapageria rosea planted in a small pot which I bought last summer, and which has grown much, but not yet flowered, and is looking well.

There is besides a miscellany of other plants, Fuchsias, Pelargoniums, Cyclamens, Myrtles, Lobelias, Sedums, Heliotropes, Petunias, Azaleas, and similar plants (with Maiden-hair and other Ferns), all of which while giving little flower in winter, always look pretty, and bloom well in the warmer and lighter months. I find, however, that Ferns of various kinds of which I have a large quantity answer best with me, being always in good health and looking very lovely summer and winter with the aid of Virgin cork, Gold and Silver Ivies, Sedums, and a few other ornamental foliaged plants, and a fountain of fairly large dimensions made by myself at little expense, covered with Virgin cork and planted all round and about with small Ferns, Mosses, &c. I maintain about 50° of heat this time of the year with plenty of moisture about in the morning, and a shade higher temperature, giving as much air as I think good on the brighter days with the stove (a gas one with some 8 ft. or 9 ft. of 3-in. piping) going while the skylight is open, and I frequently syringe overhead, watering whenever I think needful with rain-water collected in an old cask, holding eighteen gallons or so, standing in a corner of the house, and covered with cork with Ferns, &c. By these means I find the things all do well, and have no insects; never having yet found fumigation necessary, my plants are clean and free from blight.

Occasionally in the hot months I apply a little of Fowler's very effective Tobacco powder, syringing afterwards. The plants get potted every two years or so except the younger ones, which, of course, I pot oftener and keep them from weediness with occasional stoppings and cuttings. Azaleas I find do splendidly with me, being loaded with bloom without losing much foliage, while with Roses, Heaths, Coleus, and a few others which I think are peculiarly subject to blight, I can do nothing with; this is my greatest trouble, as my ambition is to have a good Maréchal Niel Rose. I have studied Shirley Hibberd and other books, but can make little out of them, having none of the elaborate appliances used by them, and not sufficient time at my disposal to carry out their suggestions, and I now go by my own ideas and experience with what tips I can get from nursery and other gardeners from whom I get my moulds ready mixed for the various kinds of plants I require them for, and lastly, but by no means least, from what I learn from Gardening Illustrated.

Vesuvius.

—— "Disappointment" has, with other amateurs, much to blame himself, for he says he reads our paper, but it is evident does not profit by its teaching. It is sure from his description that ventilation is not thought of; he waters too much or not at all; makes too much fire or lets it out. How does he kill the India-rubber plant? Let him take heart, and, if he has the opportunity, observe the way and time a nurseryman treats his plants, if at rest or growing; notice the thermometer and moisture of the house and the ventilation; if he does so, the plant he has been to buy will be a very cheap one to him. I do not write this as a professional, but as a fairly successful amateur. What I know is through the kind efforts of various contributors of Gardening Illustrated and *The Garden*. I had bought various books written by good men, but they were what so many complain of—more catalogue than instruction. As an encouragement to him, I have grown and bloomed well one dozen Pelargoniums, five or six Fuchsias, one 6 ft. high, and hundreds of blooms. I cut 125 blooms off Cacti, white, red, scarlet, and pink; Passion-flower, white and blue, hundreds; Tecoma jasminoides, large bunches; Hydrangea with white and green leaf and large bunches of flowers (white grew too big; had to give it away); Dracænas, Maranta zebrina, Clerodendron with pink flowers, beautiful Ferns and Lycopods; Correa with pink flowers; Dielytra spectabilis, Solomon's Seal, Crassula lactea, white; Euphorbia jacquinæflora, Epiphyllums, beautiful and easy; several Aloes, some now flowering; Dendrobium nobile, splendid, now in flower; Cypripedium spectabile, just flowered, lasted quite two months, and lots of other flowers. Now I never had a chance in London; had always to be at work; so knew nothing about flowers, but that they were beautiful, till a copy of Gardening Illustrated was given me, I think the sixth number; the welcome guest was entertained, and now with a timely answer to questions can get on well.—

Stroud Nisbet.

ERECTION AND MANAGEMENT OF GREENHOUSES.

Having read at different times the experience of correspondents in building and management of greenhouses, under almost every conceivable condition, I think, perhaps, a description of my greenhouse, its position, and uses might not be uninteresting; and some of your readers even might derive benefit from the statement, which I will make as concise and clear as I can. I am owner of two dwelling-houses adjoining each other, with a garden about 20 ft. long at the back. Being desirous of possessing a greenhouse I was at a loss for awhile how to make room for one in the scanty space at my disposal. At last an idea suggested itself to me, which I carried into effect. At the bottom of my small garden, as is usual in this part of the country, stands the closets, built, of course, in a substantial manner of bricks and mortar, with lean-to slated roof. Here, thought I, is a place on which to build a first-rate greenhouse, and as nobody owns the space above, I determined to build a greenhouse on the top of the closets.

First I took off the slates and laths; then I had the back wall pulled down to a level with the front wall, about 6 ft. 6 in. from the ground; then I placed thirteen joists, of 7-in. by 2½-in. timber, across the front and back walls, having the joists long enough to project about 2 ft. 6 in. over in front; then I had a 4½-in. wall built on the top of these all round to the height of 2 ft., having boarded the floor with a lot of old 1-in. boards. I then had a layer of mortar put on, and then paved with 1-in. floor quarries, the whole grouted with Roman cement, thus making the floor water-tight. I then had a frame made of 3½-in. by 3-in. timber for uprights and top and bottom rails, filled in with ordinary sash-bars about 2½ in. by ¾ in. Having placed this on the brickwork, I bedded the frame in cement and held it well down at each corner by a strong iron bolt attached to the joists underneath, to give stability to the glass structure.

Two lights to open at the top, about 2 ft. square, and an ordinary-sized door made the frame complete. In glazing, I used 374 squares of glass, each square 9 in. by 9 in. The back part, from the wall to springing-line of roof (which, by the way, is a span roof), is boarded up with 1-in. boards, thus preventing my light looking on any other property but my own. I then purchased a lot of old 2½-in. wrought-iron steam-piping and a patent heating apparatus, with smoke-pipe, &c., all complete. I placed the heater outside and directly under one corner of the projecting part of my greenhouse. Then I carried my pipes round the inside, commencing about 9 in. from the floor with the flow-pipe, gradually reducing the height so that the return pipe only stands 2 in. from the floor as it passes the door in front and goes back to the heater below. A small tank made of zinc and fixed inside the house at about 5 ft. from the floor, connected to the heater with a small 1½-in. pipe, completes the arrangement for heating. A step-ladder of ten steps, that I can remove at pleasure, enables me to ascend into my greenhouse, which stands altogether, from ground floor to ridge of roof, about 15 ft. 6 in. Inside I have stages about 2 ft. 6 in. wide by about 2 ft. high running all round the place excepting past the door, and nine shelves to enable me to place what plants I choose as near the glass as I want. As I am only a new beginner, I understood but little about the treatment of the different kinds of flowers I was desirous to cultivate; but by constantly reading Gardening Illustrated, and by the assistance of a friend and co-partner in flowers and plants, I found no difficulty in keeping my plants all right during the very severe winter of last year.

My heating apparatus worked well; I had no difficulty in keeping the temperature up to 40° even in the coldest night we had last winter. Out of about 500 plants of different roots, we did not lose 2½ per cent., and I don't think I ever saw a better display of Geraniums, Pelargoniums, Double Petunias, Fuchsias, Gloire de Dijon Roses, Primulas, Cinerarias, Hyacinths &c., than we had at the end of March last year. I planted a Black Hamburgh Vine in a 12-in. pot, but it only produced four bunches of Grapes about ⅝ in. in diameter, and then did not ripen so well as I could desire them to have done. So as soon as I had gathered the Grapes I set to and made a Vine border outside, after the manner described in Gardening Illustrated, and have planted my Vine outside the house under the projecting front, carrying the cane through the floor into the house. I have also a Maréchal Niel Rose, which has made great progress in growth of foliage, but has not yet flowered. It looks very well, and I hope to be rewarded by-and-bye for my trouble with a good supply of bloom. This year, as far as it has gone, everything looks very promising. We have about 700 plants of one sort or another, and hope to save nearly the whole of them. Cinerarais I find rather hard to manage, having grown a quantity of plants from seed, but I hope to save about two dozen of a choice sort. I have a very fine lot of Geraniums now in splendid flower, and a few Hyacinths promising very well. I forgot to state my greenhouse runs from north to south, the front facing the east, and is about 17 ft. 6 in. long, by 8 ft. wide.

Derby. A. W. W.

Gas Lime as a Manure.—The lime used in purifying gas is good material for improving cold, heavy land, and it has the effect of killing wireworm and other insects. Four tons to the acre is the quantity usually applied. In some cases it is dug in as soon as it is put on the land; in others, left during the winter, but in all cases it should be spread immediately, for if allowed to remain in heaps, nothing will grow where they have been for some time. It cannot be used with safety as a surface-dressing to cropped ground. It may be used in old garden ground with advantage, but it must not be put near the roofs of fruit trees in its fresh state.—W. E.

Pumps Getting Frozen. — At this severe season it may not be out of place to give your readers a simple method by which they can escape the annoyance of having to thaw the pump every morning. Take out the bucket of the pump over night, and by means of a piece of strong wire hooked about ¼ in. pull up the clack in the barrel of the pump, thus letting all the water in the pipe return to the cistern or well. In the morning put in the bucket, prime it by pouring a little water in from the top and begin to pump.—T. W. Y.

Cure for Lodging of Fuel in Small Vertical Boilers.—Get a common poker made by the village blacksmith about 4 in. longer than the stove is deep. Have the end beaten into a sharp point with a barb on one side extending 2 in. along the side of the poker, and 1 in. from it. An hour or two after lighting,

if the fuel has not dropped 6 in. or 7 in. down the hopper, insert the poker, and wriggle it down to the bottom of the stove, give a half turn, and draw the poker out with a short jerky motion. I had a poker like this made six weeks ago, and have not had my fire out since. —J. O. C.

GLOXINIAS FOR WINTER.

For this purpose I recommend plants raised from seed. No one who has not been in the habit of raising seedlings of those plants can form any idea how much more vigorous they are than those raised from cuttings; and for merely decorative purposes they are far superior. Several years ago I saved seeds from a flower of great substance, and of a peculiarly rich dark crimson colour, that had not, so far as I was aware, been crossed with any other variety; but the seedlings produced flowers of all shades of colour between crimson, purple, and white, but not one like the parent; in this respect they are very variable. The plants we have now in flower were raised from seed about three years ago, and the largest are in 9-in. pots; some of the bulbs are upwards of 6 in. in diameter, and if we could have spared room to have given them a shift into 12-in. pots, the plants might easily by this time have been much larger. Of course I do not say the flowers are equal to those of the best-named varieties for exhibition purposes, but many of them are large and very pretty; I am, however, only speaking of them as decorative plants for winter. I like the erect flowered kinds best, for they are more useful for cutting. The seeds should be sown in February or March in well-drained pots, in peat and sand; fill the pots to within ½ in. of the top; press down firmly, and make the surface quite smooth with the bottom of a small pot, giving at the same time a good watering. Sow the seeds thinly and evenly over the surface, and scatter over it a little silver sand. To check evaporation, and thus obviate too much watering, place on the top of the pots a little clean Moss. The seeds are so small that heavy waterings would be likely to carry them down so deep as to prevent their growing; but by giving the pots a good watering before sowing the seeds, and a thin covering of Moss, and afterwards very little water will be required till the seeds germinate; as soon, however, as the seedlings are up, the Moss must be removed, and, when they are large enough to handle, prick them off into small pots, and grow them on in the stove or a warm pit shaded from sunshine, shifting them into larger pots when necessary.

They will begin flowering about July or August; but if the object is to grow them for winter flowering, pinch off all blooms till October, when a few flowers may be obtained the first winter. About March, gradually withhold water, and allow them to go to rest. When at rest Gloxinias are treated by many cultivators the same as Caladiums, that is, they keep them dry in the stove; but in my practice in treating them as winter-blooming plants, and of course at rest the principal part of the summer, early in June they are moved out of doors, and laid on their sides in some partially shaded corner. And I find this cool treatment seems to agree with them, for the rest is more perfect, and when housed about the end of September, they have started into growth, and are ready for potting. The second season, if well managed, many of the plants will measure from 1 ft. to 2 ft. in diameter. In potting them after the first year use a richer compost. We always use for large bulbs about a sixth part of thoroughly decayed manure with the peat, and a liberal proportion of sand and small lumps of charcoal to keep the soil open. When in full growth supply them freely with water, and maintain a moist atmosphere, and when in flower, water them twice a week with weak clear liquid manure. There is no difficulty in entirely changing their period of flowering by resting them in summer, and so having them in flower from November till March, and that, too, without any special forcing, but by simply reversing their period of rest; but, as I previously stated, I find seedlings much more manageable in this respect than plants raised from cuttings, and there is a strength and vigour of constitution about them that nothing seems to injure. Thrips will attack them, and, if not stopped at once, will destroy them; the best preventive is a moist atmosphere, without absolutely dashing much water over the foliage, with mild Tobacco fumigations occasionally, whether insects are visible or not. Any one who has a few named varieties should select three or four of the most distinct, and cross them, save the seed, and give the seedlings a trial against the older kinds. Seeds of Gloxinias may also be purchased from most of our principal seedsmen. H. R.

HOW I GROW CHRYSANTHEMUMS.

Considering the rapidly increasing popularity of this charming autumn plant, and the ease and certainty with which it may be grown and flowered, a few words as to its cultivation may not be out of place. A few years ago Chrysanthemums were very little grown, but a visit to some of the exhibitions held this season will show to what extent these have come into favour with all classes. Few could look at the beautifully symmetrical forms of the incurved varieties, or the quaint shapes assumed by the Japanese class without being fired with a wish, more or less ardent, to possess a few plants and become the happy possessor of flowers at a time when there is little else to brighten up the dreary months of the year until bulbous plants are ready to lend their attractiveness to the garden. But it is no easy matter for an amateur to choose plants of the right sort, *i.e.*, those which bloom at one time. If, perchance, he had selected Red Dragon or Meg Merrilees among his Japanese, he would find that the first-named would have flowered and been over fully three weeks before the latter would have begun to open. Such a condition of things would hardly be satisfactory. But before giving a short list of suitable kinds for an amateur to begin with, let us describe briefly the mode of rearing the plants.

About the present time cuttings should be obtained and inserted in sandy soil in small pots. When only a small number is grown "thumbs" may be employed, one cutting only being placed in the centre of each pot. The pots should be placed in a cold frame, and if during frost a mat is placed over the light no harm will come to the cuttings. If, however, no frame is available the best way will be to wait until the spring, when either the cuttings should be procured ready rooted, or if not, then a tumbler placed over them will soon cause them to start. Premising, however, that the cuttings are in a cold frame during the winter, by the middle of March the plants should be shifted into larger pots, say 4-in. ones, more loam being used in the soil with some rotten manure. They must then be returned to the frame till fear of frost is past, when they may be placed in the sunniest position in the garden on a bed of ashes.

One great secret in the cultivation of the Chrysanthemum is to have the wood well ripened, without which it is impossible to obtain fine flowers; about the last week in June the plants should receive their final shift, a compost being employed of fibrous loam two parts, and well decomposed manure one part, with sharp sand to keep the whole porous. All kinds of soils have been recommended for the Chrysanthemum. Indeed, one grower of great skill and the winner of several cups asserts that it does not matter what they are potted in, "what you give them when the pots are full of roots being the more important matter." However, the compost above mentioned will do excellently for the purpose, the pot being, of course, well drained, and the plants potted firmly. The most useful size of pot for this last shift is 9 in. or 10 in. Unless tall plants are wanted, it is better to pinch them once or twice during their growth, as this keeps the plants dwarf, a great desideratum with amateurs. Few would care to have plants 8 ft. or 9 ft. high, which in some cases will be the result if the plants are not stopped. From the time the plants receive their last shift until the middle of August, all that they need is careful watering and having strong stakes to support them. If green fly makes its appearance, a little snuff dusted on the parts affected, and afterwards syringed off, will soon disperse this pest.

Strange as it may seem to the uninitiated, August is the most critical part of the whole time of growth to the exhibitor. Towards the end of this month a small or first bud will appear at the end of each shoot, and unless this is taken it is almost useless to expect flowers fit for exhibition. Taking the bud is performed as follows: As already said, a small bud will be seen at the extreme point of each shoot. Round this will also be observed three or four growths, which if not taken off would, of course, outgrow and render it useless. All these growths, therefore, must be removed as soon as long enough to lay hold of with the finger and thumb, this operation causing all the energy to be thrown into the bud. This latter grows very slowly and surely, throwing as a rule a fine flower by the middle of November. It is not advisable, however, to take buds which are seen before the middle of August. When the buds are taken the pots will have become full of roots and the plants will want feeding. All kinds of patent manures are suggested, but the best and safest perhaps for an amateur is guano. This used at the rate of an ounce to a gallon of water with a little soot in it may be given to the plants twice a week for three or four weeks, plain water (soft, if possible) being employed on other days. After this the liquid may be given every other day till the buds show colour, when its use should be discontinued. Earwigs should be watched for at night, as they soon damage the buds if allowed to go unheeded. By the middle of October the plants should be placed either in the greenhouse or indoors in the lightest position possible, and a display of fine flowers will reward the grower for all his trouble during summer.

A dozen plants, six Japanese and six Incurved, all blooming as nearly as possible at the same time, may be given as follows: *Japanese*—Elaine (white), Triomphe du Nord (red-chestnut), Baron de Prailly (rose), Gloire de Toulouse (rich light purple), Peter the Great (lemon-yellow), and James Salter (lilac). *Incurved*—Mrs. George Rundle (white), Mrs. Dixon (yellow), Mrs. George Glenny (sulphur), Nil Desperandum (dark red), John Salter (red-cinnamon), and Lady Talfourd (lilac, silvery back). These varieties are tried and well known, and are almost sure to succeed. But with regard to the Japanese, they should be pinched for the second and last time in the beginning of June. The cultivation of Anemone-flowered, reflexed, and Pompone varieties is similar to the other incurved and Japanese kinds, the only exception being in the case of Pompones, which should not be disbudded at all. H. A. R.

Chinese Primulas.—Seeds of these sown in March, in pans previously prepared, and forced in a gentle bottom-heat under a square of glass, with slight waterings when the soil appears dry, soon germinate. When large enough to handle they should be pricked off into large pans filled with a good compost, consisting of two parts turfy loam, one leaf mould, one rotten cow dung, and a good sprinkling of silver sand, all well mixed together before being used. When pricked off they may be replaced and kept close for a day or two until they root into the soil, which they will soon do if kept close and warm. When they have made three or four rough leaves, they should be potted off into 3-in. pots, small and large, according to the strength of the plants. They should then be placed in a pit or frame by themselves, when they should receive a gentle watering to settle the soil about the roots. Keep them close for a few days, when air may be given in the daytime; and, as the weather becomes warmer, a little air ought also to be left on at night. A little light shading during bright sunshine will likewise be of advantage to them. Under such conditions, they soon fill their pots with roots, when they should be shifted into 3-in. pots, and placed in a cool frame; and, if facing the north, all the better, inasmuch as shading will not then be needed, but if facing the south, the lights may be whitewashed, and tilted on their sides, care being taken to have them so that wind will not injure them. Plants treated in this manner will show bloom in September, and, if required, may be allowed to flower at that time; but if not, the flower-stalks should be picked out as they appear. In October, they should be removed to a light airy house, at the same time giving them a top-dressing of rotten cow-dung, broken into small pieces. The latter will be found to afford them great assistance. In watering, care must be taken to only give

just sufficient, as damp is their greatest enemy. Plants, treated as has just been described, will bloom from November to February; and, by sowing for succession again in May, and growing them on as the others have been, this Primula may be had in bloom till next May if well attended to.—W. W.

TENDER ANNUALS FOR THE GREENHOUSE.

SEEING the great dearth there is of greenhouse plants that bloom during the summer and autumn, and the few available for decorative purposes at those seasons, with the exception of Fuchsias and Pelargoniums, it has occurred to me that a list of such plants as may be raised from seed sown in March or April, together with a few remarks thereon, may be of service to readers of GARDENING. One advantage in growing plants of this class is that they can be got up quickly at a very small cost, and as fresh ones can be raised every spring, there is no necessity to winter them, a great consideration with many who have only very limited accommodation under glass, and who therefore desire to make the most of the room they have.

Amarantus tricolor, salicifolius, and Henderi are very desirable, and come in admirably for room decoration, but to fit them for this purpose they must have plenty of light, so as to impart to their leaves those rich, brilliant tints of colour for which they are so justly admired. Not only must they have an abundance of light, but the atmospheric moisture should be in proportion, otherwise they are sure to suffer from the attacks of red spider, to which they are very subject, and which, if not kept in subjection, soon spoils their beauty. The best and easiest way of growing these Amarantuses is to plunge them in a pit or frame by themselves, and keep them well syringed overhead, and if this is done daily at two or three o'clock when shutting them up, they will soon make handsome little specimens that will be highly ornamental in the greenhouse or conservatory. Being moisture-loving subjects, they should have plenty of water and free drainage to admit of it passing away quickly, and this, with a rich loose soil and liquid manure occasionally, will keep them in perfect health till cold weather sets in, when they begin to die off. Seeds sown in April in heat will soon be up, and, in potting off the plants, the most promising only in point of colour and habit should be selected, as they are very sportive in their character, and vary much in their markings.

Globe Amarantus.—The flower-heads of this resemble those of Clover in shape and size, and are rich and varied in colour. The group to which it belongs contains plants well deserving of cultivation; when well grown they form neat, branching, bushy little plants, varying from 1 ft. to 2 ft. high, each shoot terminated with one or more symmetrical globular heads. These, if cut before they have attained their full size and maturity, will retain their fresh-looking appearance for a considerable period, and are, therefore, most useful to mix with Everlastings and Grasses of different kinds, with which they associate well and do much to enliven. These Gomphrenas are of easy culture, and do best when growing if placed in a pit or frame where they can be plunged in a bed of gently fermenting material, the genial moisture from which, being discharged with such regularity, just suits them. The next situation most agreeable to them is a warm house, where they can be placed away from draughts or dry currents of air, and kept syringed occasionally until they show flower, when any damping overhead should be at once discontinued. To have fine masses of them, the best way is to put three plants triangularly in 6-in. or 8-in. pots, and, if the different colours be grown together, they form a pretty contrast, and have a much better effect. Those that blend best are the purple and white or purple and yellow, both of which come true from seed, which should be got at once and sown in a brisk heat, and the plants nursed on in the same near the glass so as to keep them from drawing up weakly and spindly. They delight in a rich vegetable soil, and require plenty of water all through the season, the want of which soon causes them to present a starved appearance, and prevents them from producing their blooms with anything like the freedom or size they otherwise would do.

Browallias (elata and Roezli) are most valuable for blooming late in the autumn or through the winter, which they will do freely if kept near the glass in a temperature varying from 50° to 55°. For working up into bouquets they are unsurpassed, their slender stems and numerous lovely small blue or white flowers rendering them particularly well adapted for that purpose, and, what is equally in their favour, they are very lasting in water, as, when using them last year, I found at the end of a week they were as fresh as ever. As pot

Browallia Roezli.

plants, too, they are exceedingly ornamental, and, in order to have a regular succession, seed should be sown about the middle of June and again at the end of August or even later, which will carry on the supply up to the following April or May. Those sown first will do best grown outdoors after they have got a fair start, which should be afforded them by keeping them close in a frame for a few days after being potted, when any sunny sheltered position will suit them. Being rather spare and fragile in their habit, they produce the finest display by being placed three in a 7-in. or 8-in. pot; but those required for winter work may with advantage be confined to a size smaller, as then less water and root room are required. During the summer months they require a free use of the syringe, as in hot weather they are subject to red spider, which, if allowed to effect a footing, soon spoils their appearance.

Rhodanthe Manglesi is one of the prettiest of all annuals for decorative purposes indoors, and forms charming, neat little groups for small stands or vases, where, when laden with lovely pink, satiny-looking flowers, it is highly effective. The newer variety, named Prince Bismarck, is likewise very desirable, being more double and having the merit of lasting longer in bloom. To get them to bloom early in spring, at which time they are most valued, seed should be sown in August, and the plants wintered on light airy shelves near the glass in a warm house where the temperature does not fall much below 50°. Raised in spring they will flower in two months or so hence, and last till late in the autumn. Rhodanthes delight in rich vegetable soil, and should be potted in a mixture of at least half leaf-mould or peat and loam in well-drained pots. Any cold frame, where they can be shut up early, will suit them at this season if not kept far from the glass.

Celosia pyramidalis produces splendid feathery plumes, ranging in colour from bright crimson to pale yellow, and the plants are of singularly graceful habit, the inflorescence drooping over in the most elegant manner, and having such a velvety appearance, they are exceedingly showy and attractive. Compared with these, the old Cockscomb, from which these originated or are allied, is a stiff, formal-looking plant, and is fast losing favour, as these are so much better in every respect. When well grown they form grand-looking decorative subjects, and are most valuable either for the greenhouse or conservatory; besides which, they are especially suitable for cutting, as, owing to their peculiarly dry nature, they last quite fresh-looking for a considerable length of time either in or out of water. Seeds sown now will afford plants that will come in towards the end of August, and these in a warm house will last in full beauty till quite late in the year. No place suits better to grow them in than a pit or frame, where, if closed early and heavily syringed, they will keep clean and soon make fine plants. Their habit is so symmetrical and their growth so uniform, that they require no stopping or training, and should be allowed to take their own natural course entirely, as it can in no way be improved.

Martynia fragrans is a very desirable annual for pot culture, affording large, tubular, Gloxinia-like flowers that are beautifully spotted and marked, and altogether of a very showy character. Being somewhat tender, it is necessary to raise it in heat and grow it on in the same temperature till it comes into bloom.

Balsams are too well known to need a word in their favour, as they are grown more or less successfully in almost every garden, and if a good strain be obtained, and the plants well managed, nothing is more showy and beautiful than those of the Camellia-flowered section; besides having blossoms of great size and fulness some of them are as handsomely marked as a Carnation, while others are of a brilliant self colour. To have fine, sturdy, well-furnished specimens, with the lower branches resting almost on the rims of the pots, they must be grown in full sunlight, close up to the glass, and have plenty of air on all favourable occasions. This will keep them stocky and short-jointed, so that every branch and lateral will stand stiff and erect without any support, as all Balsams should. To grow them really well they require a little bottom-heat, such as may be afforded by any gently fermenting material, and at every shift into larger pots they should be dropped lower, so as in the end to bury up the stems to the first joint. So gross-feeding are they in their habit that they will take almost any amount of liquid or solid manure if administered in a mild form and at proper and suitable intervals of time. When large plants are required it is a good plan to pick off the first bloom-buds that show, as then their strength and energy are concentrated in developing growth and in becoming better established.

Petunias.—Of the many plants that may be raised from seed and got up to a flowering state in a very short space of time none are more generally useful than the double Petunias,

Dwarf Single Petunia.

which, grown in pots in an open position outdoors, flower with the greatest freedom when brought under glass, and, being so rich and varied in colour, do much in making a house gay and attractive. Even the single forms are deserving of cultivation for the same purpose, so beautiful are their markings, many of them being marbled and striped in the most fantastic manner possible. By keeping them plunged in a sunny spot they can be brought in as required, and a constant succession kept up till Christmas or later. If sown early in spring they may be had in flower two months hence, but if large plants are required the way is to nip out the points of the shoots and give them a shift into

larger pots. The soil that suits them best is a good fibry loam, in which they should be potted firmly and not over-drained.

Lantanas are exceedingly showy, free-flowering plants that come in admirably during the summer and continue on till quite late in the year. The trusses of these are generally borne in pairs and have much the appearance both in size and shape of Verbenas, but are richer in colour, and the habit of the plants more bushy and woody. For greenhouse or conservatory decoration they are of great value; the only drawback they have is that they are anything but pleasant when touched or rubbed against, as they then exhale a rather disagreeable odour. Seed should be sown in spring, and the plants pushed on in heat in full sunshine, as it makes the growth short-jointed and hard, and induces an abundance of flowers.

Schizanthus papilionaceus and retusus form beautiful pot plants that bloom profusely and are highly ornamental, especially the first-named, the flowers of which bear a close resemblance to butterflies, so rich are their markings. Both varieties are very bushy in their habit, and range from 1 ft. to 2 ft. high, so that they are well adapted for small houses and for window decoration, where, from their gay and varied colours, they are sure to be highly appreciated. Sown in autumn, they are easily wintered in an ordinary greenhouse, and then come in at a time when flowers are scarce. To have fine specimens they should be grown three in a pot, and if of mixed colours, as they are almost sure to be, they will be all the more interesting and make a better display. Schizanthuses are plants of very easy culture, and will do well in almost any kind of soil that is open and free.

For the roof of the house where a few strings or fine wires can be strained Ipomœas may be grown, but these must have a sunny position assigned them to induce them to flower freely. Tropæolums, too, of the better class form showy roof-climbers, and when restricted for root-room, as they are in pots, are exceedingly floriferous, so much so, indeed, as to be rarely out of bloom. It will thus be seen that by the expenditure of a few shillings for seed, a greenhouse may be filled with gay flowers to take the place of Camellias, Azaleas, Epacrises, and such like when they are set out-of-doors to ripen their growth. Besides those enumerated, there are many others that might be mentioned, but these are some of the best. S.

Wintering Bedding Plants.—I never had bedding plants in better condition at this time of the year than I have them now, and I never had plants that were less coddled. With the exception of a few odds and ends, all our stocks of these plants are in boxes 2½ ft. long, 1 ft. wide, and 3 in. deep. Each box has six holes in the bottom, large enough to put the finger through. In the second week in August a piece of crock was put over each of these holes, the boxes were filled with a mixture of loam, leaf-soil, and sand, and then about fifty cuttings were put into each. As soon as the cuttings were put in, each box was watered and set outside, fully exposed to sun and air. Here they remained until the middle of October, when they were shifted into a Vinery, from which the Grapes were just cut, and there they are now. From being so much exposed to the air, the plants are not drawn up; on the contrary, every one of them is dwarf and bushy, and no dead leaves have yet been gathered from them. A little artificial heat is admitted two or three times a week, and the top and bottom ventilators are open night and day, unless it is extremely cold. They are not watered oftener than once a week, sometimes not so often. It is not the hardiest of green-leaved Pelargoniums that are thus treated, but many choice variegated ones as well. Alternantheras are often found to winter badly; hundreds of them were put in boxes like the Pelargoniums; they were rooted in a close frame, and then hardened off. They are now along with the Pelargoniums, and so luxuriant that not a particle of soil can be seen, looking down through the plants, and they are so bushy that the little branches are hanging over the sides of the boxes. Mesembryanthemum cordifolium is equally healthy under the same treatment, and so are the different kinds of Iresines. I attribute all this chiefly to growing them hardy at first, and afterwards not putting them into any close place to make them tender before the winter had set in. Last year most of our Pelargoniums were rooted and wintered in small pots, and it took four times as much space to accommodate the same number of plants in that way as in the boxes, and I find that they keep much better in the latter than in pots. In March the Pelargoniums will be potted into small pots, and the Alternantheras given more room in the boxes in which they are now growing.—C.

COLOCASIAS.

THESE are hothouse plants closely allied to the Caladium. They are Indian herbs with tuberous roots, and are grown in gardens for the sake of their handsome foliage. Colocasia antiquorum, which we now figure, is cultivated largely in Egypt and India for the sake of its leaves, which are boiled and eaten as Spinach.

Colocasia antiquorum.

Some of the varieties, such as C. macrorhiza (the variegated form of which is very handsome), are grown for the sake of their roots (which contain a large amount of starch), which are used as well as the leaves as food. These Colocasias are easily propagated from suckers, which are produced plentifully from established plants. In the matter of soil for Colocasias, it is hardly possible to make the material in which they grow too rich; one-half yellow loam to an equal proportion of thoroughly rotten, dry manure and one-sixth sand, will in every way suit them. In selecting young offsets of C. macrorhiza variegata, those should be chosen that have somewhere near an equal proportion of green and white in their leaves; suckers with too great a preponderance of white are deficient in vitality to grow freely, whilst, on the other hand, those that contain too much green in their early stages seldom attain colour enough to make them attractive.

A warm moist temperature and abundance of water at the roots when growing freely are necessary if large and handsome plants are desired, and when the pots are full of roots, a top-dressing of well rotted manure, or frequent supplies of manure water, will be of great assistance.

FRUIT.

How to Grow Late Grapes.—In the cultivation of late Grapes there are many points which should receive forethought, not the least of which is, how the best return can be produced at the least cost in fuel, which is a very heavy item in the garden expenditure of the present day. Before taking this part of the subject into consideration there are other details upon which I would like to say a word. After the Grapes are cut and carefully stored away in dry fruit rooms, the Vines should be pruned without delay; and in pruning I think a wise discretion might be exercised in many cases, not in cutting upon any particular principle or upon any mathematical calculation, but upon a system the result of experience acquired by studying the conduct of the different varieties of Grapes grown under different conditions and circumstances. There is no doubt that soil, climate, and other circumstances have a very potent effect, either one way or the other, in the production of Grapes; so also has the amount of light to which the wood of the Vine is exposed. If this important factor in Grape culture be minimised by encouraging more spurs, and consequently more leaf growth than can be fully exposed to the direct action of sun and light, the results will—must, in fact—be less satisfactory than they otherwise would be. In pruning our late Vines this year I have been struck with the varying conditions of growth, its character and solidity, in several varieties of Vines of more or less robust habit, where influence of sun and light had most play amongst the wood and foliage and where the spurs had not been too thickly set on the Vines. I also noticed, in strong growing varieties like Trebbiano, where a latent eye pushed away a weakly growth which was encouraged, how solid and thoroughly ripened it was to the core as compared with strong shoots on the same Vine from spurs on either side of it. Practically, then, pruning is an operation to be learned by experience of no superficial character, for not only do Vines vary in habit in different soils, but the houses in which they grow also alter their condition a good deal. Vines which are grown in low, badly ventilated houses should not be planted nearer to each other than 3 ft., and the spurs, where they are grown on the spur system, should be 18 in. apart; they should also be started into growth a month earlier than Vines which are more favourably situated in light, airy, lofty houses. Of course exceptions would occur in the case of Vines such as Lady Downes, which scalds so bady in hot weather. This variety may be grown at 2½ ft. apart, and the spurs might be allowed to grow closer, in order that the foliage might shield the berries from sudden blinks of strong sunshine. Another matter worthy of consideration in the case of vigorous-growing Vines is that they should not be too much "curbed" by stopping where there is anything like a fair

opportunity of giving them headway, nor should they have over-stimulating food supplied to them while they show a disposition to grossness. Plenty of clear water at the roots will be sufficient for them, and with a long season of growth they will settle into a free-bearing state, which cannot be expected from the practice of late starting and a system of cultivation which induces soft pithy shoots. Vines are often retarded in spring on the plea of economy, but I fear the fact is lost sight of that it takes more fuel to finish off crops in a dull sunless autumn than it would to give them an early start in the spring, to say nothing of the superiority of solar heat over the artificial warmth that can be obtained from hot-water pipes.—W. H.

Winter-flowering Fruit Trees.—Wherever fruit trees are much subject to the attacks of aphides, scale, Moss, or Lichen, a suitable winter dressing will be beneficial. For the eradication of Moss, fresh lime is the best and cheapest material to apply; it may be dusted on when the branches are slightly damp, or it may be applied in a liquid form through the syringe or garden engine. In either case a fourth part of soot may be added to it. Soot in any shape is a capital stimulant for fruit trees, and might with advantage be much more extensively used than it is, either as a top-dressing to the roots or as an insecticide. When applied in a liquid form, it should be strained, just previous to being used, through a piece of canvas, otherwise the syringe or engine may be rendered unserviceable. For the destruction of scale and aphides, Gishurst Compound, in the proportion of 8 oz. to the gallon, may safely be used dissolved in soft water. The common and, as I think, the best plan is to thicken the liquid compound with lime and soot, and a couple of good handfuls of sulphur per gallon till it has the consistency of ordinary paint, and then put it on all the branches of the trees with a soft brush, rubbing it well in on the old wood, but passing over the young shoots with a lighter hand, so as not to disturb any of the buds, drawing the brush along in the direction of the buds only without any reverse action. It has been stated that to simply wash the branches of the trees with the liquid compound without any thickening ingredients would have the same cleansing effect. I have tried both ways, and the conclusion at which I have arrived is that the thicker mixture has a more lasting and beneficial effect than the thin one, and as one can be applied nearly as quickly as the other, and there is not much difference in the cost, I should recommend a continuance of the old system.—H.

How to Grow Cranberries.—I have had for a good many years two flourishing beds of the large-fruited Cranberry, which has gone on fruiting abundantly from December till the end of spring, and pushing its trailing shoots in every direction, with no other soil than the natural one, and no more irrigation than what the rainfall yields. One of these beds stands on a dry, sandy hill, while the other, at a short distance off, is more flat and moist, and I should imagine that the success of both would have been about equal had not the latter one been allowed to be too much overrun with Heather, Brambles, and other intruders; now that they are cleared this bed seems to be starting fair with the other. I fancy the truth to be that where Heather is the weed of the soil the Cranberry will probably not refuse to grow. The Heather (Calluna) is always pushing out its growth among my Cranberries, and has to be kept back, while, on the other hand, the long shoots of the Cranberry are extending themselves among the masses of Heather and Heath which fringe one of the beds.—A. J. B., *Kent*.

Protecting Garden Tools from Rust.—For garden implements of all kinds, having metal surfaces exposed, and even for knives and forks, and other household apparatus, indeed for all metals likely to be injured by "rusting," we know of no simpler, more effective application than the following: Take any quantity of good lard, and to every half-pound or so, add of common resin ("rosin") an amount about equal to half the size of an egg or less—a little more or less is of no consequence. Melt them slowly together, stirring as they cool. Apply this with a cloth or otherwise, just enough to give a thin coating to the metal surface to be protected. It can be wiped off nearly clean from surfaces where it will be undesirable, as in the case of knives and forks, &c. The resin prevents rancidity, and the mixture excludes the ready access of air and moisture. A fresh application may be needed when the coating is washed off.

THE COMING WEEK'S WORK

Extracts from a Garden Diary.

January 31.—Sowing a few Sweet Peas and Syon House Cucumbers; potting off Melons and plunging them in sawdust to keep them from slugs; also potting off some Mignonette for Tree Mignonette and placing it in a cool place; pricking-off Lobelia speciosa cuttings; putting in some double Senecio cuttings; also those of Coleus and of Centaurea gymnocarpa, C. candidissima, and Stephanotis; putting in likewise more cuttings of Petunia, Verbena, Cerastium, and scented Verbena; planting Box trees in shrubbery borders; also some Cauliflowers under hand-glasses, giving three shovelfuls of manure to each glass; likewise some Horseradish on ridges, laying the thongs horizontally; covering up some Rhubarb and Seakale with boxes and embedding them in leaves; shifting Borage into larger pots to get it into flower; finishing nailing Apricots and beginning to nail Peach trees.

February 1.—Sowing Walcheren and Early London Cauliflower in frame; also Capsicums and Chrysanthemum carinatum fl.-pl.; potting off Heliotropes and Gazanias and placing them in heat; potting Rhododendrons in peat for forcing; potting Disa grandiflora in peat; putting in another batch of Asparagus; red-leading Peas before sowing to keep birds off them; putting ashes over Peas just coming up; putting some manure to Asparagus beds; mixing up some manure and leaves for Cucumber pit; making a new Vine border for good sandy turf only; sooting between rows of Cabbages; stirring up the soil about young Mignonette; top-dressing Peppermint beds with leaf-soil; looking over wall tree coverings, making new ones, and repairing old ones; making canvas coverings for Green Gage Plums; earthing up the first Peas.

Feb. 2.—Sowing Bromham Hall Melon, Parsley, and Viola lutea; potting Salvia splendens and Gnaphalium; putting in more cuttings of Achyranthus, Fuchsia, Scutellaria, and Tropæolum called Crystal Palace elegans; putting in another forcing of Rhubarb; putting a few pots of Musk in heat; looking over Apple stores; top-dressing pot Vines with manure; levelling Vine borders and putting on a dressing of bones; making some frames ready for Heaths; clipping Holly hedge.

Feb. 3.—Sowing Wigandia and Phormium tenax; also East Lothian Stocks, Nasturtium canariense, Petunia, Cyclamen, Golden Feather Pyrethrum, and Rhodanthe; also sowing Chilies, Borage, Marjoram, Basil, Egg Plant, and Tomato; potting cuttings of Croton variegatum, Salvia patens, first-struck Fuchsias, Verbenas, Mangles' Pelargoniums, and second-sown Cucumbers; putting old Fuchsias into heat for cuttings; manuring Black Currants

Feb. 4.—Sowing Verbena venosa, Chamæpeuce diacantha, Echeveria, Melianthus, and Cineraria acanthifolia; potting Gazania splendens; putting in a few cuttings of Lavendula dentata; also some Willow cuttings; planting four lights with sprouted Ashtop Potatoes; dusting Plum trees with soot, as birds are injuring the buds; earthing earliest Potatoes.

Feb. 5.—Potting Gloxinias and Caladiums, and putting them into moist heat; dipping Strawberry plants for green fly; camel-hair brushing flowers of Strawberry plants; topping and otherwise trimming Turnips, and placing them in a cool place in ashes; top-dressing Peach trees in pots with half cow manure from farmyard and half-burnt refuse; cleaning up wood-walk sides

Glasshouses.

Examine Cinerarias, Calceolarias, and Pelargoniums particularly, in order to see that they are free from aphides, for if a single plant be infested by them, they will spread in all directions, giving immeasurably more trouble than if prompt means were taken to destroy them as they appear. There are many hard-wooded plants, such as Boronias, Polygalas, Tetrathecas, and Aphelexis, upon which aphides will live, although they do not thrive, and yet upon such plants, especially Aphelexis, they are much more difficult to kill than when upon plants for which they have a greater liking, so much so, that Tobacco smoke, when applied in strength and sufficient quantity to destroy them on soft-wooded plants, has next to no effect on them. In such cases nothing equals a couple of washings with good strong Tobacco water, allowing it to dry on the plants and not washing it off, as is sometimes recommended; this will generally be sufficient to kill not only the mature insects, but also their eggs. A few Gloxinias and Achimenes should now be started; pot the Gloxinias in good loam, to which add some sand and leaf-mould. Achimenes are best treated as follows—Get some seed-pans, drain them, and let the soil used consist of three parts sifted loam and one-fourth of leaf-mould and sand. By using material of this description their roots do not get broken when shifting them into the pots in which they are intended to bloom. They will be ready for potting when they have grown 2 in. Both Gloxinias and Achimenes should be accommodated with a temperature of not less than from 60° to 65° at night, with a rise of 6° or 8° during the daytime. Till they commence to grow and push leaves they must receive no more water than will keep the soil slightly moist; they are apt to rot if too much be given them.

Preparation for Potting.—It is now time to see about potting some of the earliest started stove plants, and soil should at once be prepared. In all cases not only ought it to be in a medium condition as to moisture—that is, neither too wet nor too dry—but it is a matter of great importance that previous to use it should be so warmed as to bring it up to something like the temperature of the house in which the plants are growing, for to place a body of cold material, in the way in which it is frequently done, in contact with the roots, has a most injurious and stagnating influence on them; but in thus preparing soil, great care should be taken that it is not overdried, as experience points to the fact that when soil is placed in close proximity to a heated surface whereby it becomes too dry, the essential elements of fertility are dissipated. To look thus narrowly at what might be termed by many trivial matters may seem unnecessary, yet it is attention to small details of this kind that makes the difference between complete or partial success. Where no convenient place exists for warming the soil, it may be put into boxes and placed over the hot-water pipes. If a calculation be now made as to something like the quantity of peat and loam that will be needed during the next month or two in the repotting, it can with advantage be at once so far prepared by breaking it up with the hand, not sifting it, and reducing it to different sizes, in proportion to the large or smaller description of plants that require shifting.

Caladiums.—It is desirable to start these at two different times, by which means a portion may be had late in the autumn, with handsome, healthy foliage, at a time when the earliest grown plants have lost their colour. In potting, it is well to consider whether large or small examples will be the most useful, for in no case is it advisable to over-crowd the pots, as, where this occurs, the leaves will not acquire their wonted size. They will succeed in either loam or peat, but the foliage possesses more substance when grown in loam than in peat.

Poinsettias.—Plants of these that have done flowering should receive no more water at present; they should be stowed away in any place where there is an intermediate temperature for some time, until they require to be started again into growth.

Ardisias are most useful when comparatively small and fully furnished with leaves to the base. Any that are getting too large and that have lost their lower foliage should now be headed down and put into a brisk heat, where they will at once make several shoots. When these have attained a few inches in length all but one can be taken off with a heel and struck. They will make good small plants much quicker than seedlings. The stools may then be partially shaken out, repotted, and grown on with a single stem, a way in which they look much the best.

Amaryllises, &c.—Where a good stock of these is grown it will be better to have them in succession than in bloom all together. A few of those that completed their growth earliest in the autumn, more particularly the deciduous species, if now subjected to a brisk heat, will push up their flowers quickly. The soil should receive a good soaking of tepid water, or, if the plants be plunged in a moist bottom heat, and water be supplied in the usual way, it will be sufficient. Plants of Eucharis amazonica that have been rested with a view to coming into flower after those earlier started should be brought into the warmest end of the house, and if possible plunged in bottom-heat, and if they are strong and in good condition, they will at once push into bloom. Imantophyllums, although more correctly greenhouse subjects, are very effective for general decoration brought into flower earlier than usual by the application of more heat.

Miscellaneous Plants.—Plants of the handsome Aphelandra cristata that flowered last autumn should now be kept in the stove to encourage their making young growth for purposes of propagation. Of Eranthemum pulchellum, Plumbago rosea, Scutellaria mocciniana, Sericographis Ghiesbreghtiana, and Thyrsacanthus rutilans, a sufficient number of such as have done blooming should be cut back and placed in the stove, where they will be induced to make growth for cuttings. They should have plenty of light, so that the young shoots may be short and stocky, as upon that very much depends their making stout, healthy plants for blooming next autumn. After the first flowering of Euphorbia jacquinæflora is over it will, if kept sufficiently warm, make a second growth that will bloom, and, although the sprays will not be so large as the first, they will be useful for cutting.

Orchids.—The greater portion of the spring and early summer-blooming Odontoglossums will now be pushing up their flowers, and continuous watchfulness will be necessary to see that these do not become a prey to slugs or cockroaches; the latter are not usually so troublesome here as in the warmer quarters afforded by the hotter houses, where they increase faster and find more congenial hiding places, but the slugs and snails need to be unremittingly sought after, for, even if destroyed until there is no trace of any remaining, there are others that soon find their way into the houses, come into existence from eggs already deposited there, or that get in with the potting or other material from time to time introduced. Such species as O. citrosmum, O. hastilabium, O. Phalænopsis, O. vexillarium, and O. Roezli will need keeping in a warmer position than the least heat-requiring kinds. Masdevallias which have not yet completed their growth must have sufficient water to keep their roots thoroughly moist, for their requirements in respect to moisture are almost equal to those of real aquatics, and, provided the material in which they are grown is of a nature to allow the water to pass freely through it, the growths are generally finest where the most water is used.

Flower Garden.

Auriculas.—Continued severe frost prevents anything being done to these at present; the frames are covered at night with mats, and this must be done every night while frost remains. Those who have a heated greenhouse in which to place their plants have a great advantage over those who can only obtain ordinary frames. They ought to be placed in the house this week, and frosts should be excluded.

Carnations and Picotees.—It ought to be well known that these do not seem to be in a dormant state, even at mid-winter. If the weather be mild they make roots and slowly develop leaves. During frosts so intense as to crust the soil in the pots growth either above or below ground must be suspended. Growers of these flowers do not give them that amount of attention which they require during the winter months, and which is especially necessary in February; the plants sometimes begin to spindle for bloom the first week in this month; these will be early blooms, and, if the weather be mild, such plants should be carefully repotted into their blooming pots. The main collection will not be ready for potting until the end of the month. Have all the plants thoroughly cleaned before potting them; dead and decaying leaves are unsightly, and must be carefully removed; even in the best-managed collections they are to be found. If sparrows are numerous and short of other food they will peck the tender points out of the plants; if so, it will be necessary to place a net over them as the best precaution. No trace of aphides should be allowed on the plants at this date; it is very dangerous to fumigate the frames after active growth has commenced.

Dahlias.—If a large stock is required the roots must now be placed in heat after they have either been potted singly, or a number of roots placed together in suitable boxes. The best place is a forcing house, where the temperature ranges from 50° to 55° at night. They may be placed over the pipes in Vineries or Peach houses, and be started with them. The shoots start well and healthily over a bed of leaves or tan with just a mild heat.

Hollyhocks.—See that leaves on plants placed in heated houses do not become infested with red spider; injury is often caused by it before the discovery is made. Seedling or common sorts that were planted out in the autumn must not be quite neglected. If the plants have been mulched round the roots, this forms a safe hiding place for slugs, which will eat the leaves, and it is also very desirable to run the hoe through the ground if it is moderately dry. While frosts last nothing can be done.

Phloxes in Pots.—Start the shoots into growth in order to obtain early cuttings. The heat of a greenhouse will cause a very early growth. Shoots about 1 in. long may be slipped off and placed singly in very small pots. They will soon form roots, and grow away freely with a little bottom-heat. Those in beds cannot require any attention until the weather is more favourable.

Pyrethrums, Delphiniums, &c., in beds, will be putting forth their very tender leaves as soon as the frost will allow them. See that they do not receive any injury from birds. The plants may be lifted and divided if it be necessary to increase the stock.

Polyanthuses.—As a rule, the treatment recommended for Auriculas applies to these. We would remove this class of plants to a cool greenhouse near the glass if it were possible to find room for them. The soil in the pots has been frozen for a considerable time now, but the flowers are most injured by birds in this early stage of development.

Pits and Frames.—Fresh stable manure, sufficient to make a good bed for a one or two-light frames in which to raise Cucumbers and similar plants, as well as for making beds for Radishes, Potatoes, and early Carrots, ought now to be got together; it is well to mix the manure with as much in bulk of leaves, as when thus mixed it does not heat so excessively, is ready to use sooner, and keeps its heat better than when manure only is used. The material for these beds, whether it is manure alone or mixed, must be shaken, thrown into a heap, and watered if necessary. In this state let it remain for five or six days, then turn and shake it, an operation which ought to be repeated a second time in a similar way soon afterwards. Rhubarb that is growing must have plenty of water, for if neglected at all in this respect it will not come nearly so strong as if properly attended to. Seakale roots after being forced ought to be put in sand or ashes; if there be a scarcity of young roots for planting some of these will do when the time arrives for putting them in. A little Lettuce and Cauliflower seed should now be put in in boxes and placed in a house or pit in which there is a little warmth, if not in a cold frame in a sunny situation where, when the plants are up, covering material can be used for protection if required.

Fruit.

When once the frost releases his grasp vegetation will make rapid progress; it is therefore important that all pruning should be completed as soon as possible, for, to say the least, it seems unnatural to prune when the buds are expanding, and such an operation carried on then must tend, in some degree, to produce constitutional derangement. As regards neglected orchard trees, many would be the better for having their root and stem suckers removed, cankered branches cut off, and other branches thinned out, together with any long spurs, in order that the trees may have a chance of renewing their vigour by the production of new wood; any trees that are affected with Moss or Lichen should be splashed over with a mixture of soot and lime, a simple but sure remedy. A liberal surface dressing of either fresh soil or manure should afterwards be given, and even the first season the fruit will be so improved as to well repay the outlay. Autumnal planting of fruit trees is always preferable, but if not done let all be in readiness for doing such work as soon as the state of the soil permits; planting when the soil is in a sodden state is ruinous, no matter how well drained the soil may be. For obvious reasons, in stiff or clayey soils the plants should be raised a few inches above the ground line, but in light or gravelly soils they are best planted on a level with the surface, care being taken that in neither case the stems are buried too deeply.

Vegetables.

All other things being equal, a well-drained and deeply-trenched garden will yield double the produce of an undrained and badly-cultivated one. The first neither suffers from wet nor drought. The crops can be got in at the proper time, and they require but little cultural attention afterwards, and that little is the more expeditiously accomplished owing to the workable state of the soil in almost all weathers, consequently the crops are finer and earlier matured, whilst, in a garden of an opposite character, seed sowing has to be deferred through the unkind state of the soil, and this late sowing, coupled with the slow progress made by reason of the water-logged ground, and the difficulties of culture through the ground getting hard and baked by the first dry weather, tends to show the economy there is in deep trenching and effective draining, a large proportion of which may be done in weather when it is not practicable to do aught else. No excuse should be attempted for the neglect of such a duty; moreover, an earnest determination to accomplish it will bring its own reward in the form of assured success. We are still frozen out, but as soon as a change occurs, and the ground can be worked, seed sowing should proceed with dispatch. After a few early Peas, Beans, and Carrots have been got in on a warm border, space for the main crops of Onions and Parsnips will require attention; both of these flourish best if sown as early in February as circumstances permit. Drill culture is greatly preferable to sowing broadcast for all kinds of kitchen garden crops. The space apart of the drills for Onions should be at least 12 in., and for Parsnips 15 in. The ground for Onions cannot be too highly manured or deeply trenched, but previous to sowing it should be rolled to make the surface firm. Parsnips, on the other hand, cannot have the soil too open, and the manure for these should be buried rather deeply, for no matter how much so they will search it out. Surface manuring for these has a tendency to the production of forked or malformed roots, so that it is better not to manure at all in soils of good or medium quality than to have it immediately under the top spit.

TOWN GARDENING.

WINDOW GARDENING.

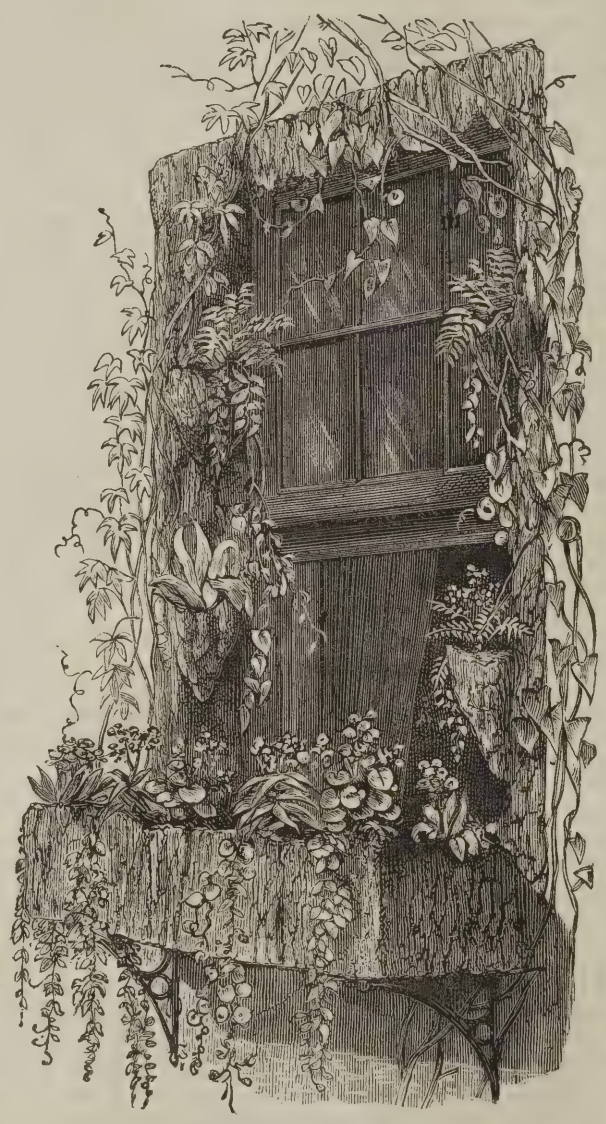
Potting, Watering, &c.—For the benefit of those who are not acquainted with the *modus operandi* of potting we give a few hints upon the proper method of performing this and other similar operations. We have found that it is better, as a rule, to do all potting in spring, instead of autumn, as is the usual practice. If any shifting, &c., is obliged to be done at the approach of winter, get it done in good time, not later than September, so that the roots may be feeling the sides of the pots before the trying season comes on. Of course an exception must be made in the case of all bulbs for spring-blooming Hyacinths, Tulips, &c., which should be put in the soil in September or October. The most important point in potting is to have everything as clean as possible, pots and crocks all scrubbed both inside and out, and rinsed in clean water afterwards. You cannot grow healthy plants in dirty pots. These must also be perfectly dry when used as well, or it will be as bad or worse than if dirty. The soil must be sweet and fresh. It should have been stored under cover, but exposed to the action of the air for some time before use, and should never have been allowed to get either wet or dust dry; least of all should it be in either of these states when used, but just in such a state that a handful taken and squeezed together should only just stick together till touched, and then fall to pieces again. Having your pots and soil all ready, put a largish piece of crock over the drainage hole, then two or three smaller pieces, and then a sprinkling of bits about the size of a small bean. Some plants, especially those that require an extra abundant supply of water, need more drainage than this; also in the case of pots for seeds or cuttings, which should be nearly or quite half full of drainage, but for most things this will be sufficient. Over the crocks place a handful of green Moss or spent Hops, to prevent the fine soil washing down and clogging the drainage, and then some of the rougher parts of the

soil. Now if you are merely shifting the plant, that is, transferring it from a small pot to a larger one, and if it has not been very long in the former, merely turn it out, reversing it on your hand; remove the old crocks, also any loose soil, dead roots, or Moss upon the surface, and set it in the new pot, so that the old surface shall be only just covered by the new; fill in the soil all round, pressing it in pretty firmly; it is a good thing to use a flat-ended piece of lath for this purpose round the old "ball," as it is called. Do not make the soil, however, very hard, especially if a rapid growth rather than early flowering is wanted, or if the plant will have to stay in its present pot for any great length of time. Finish off the surface nearly level, but for Fuchsias, Geraniums, and other plants that require a liberal supply of water, and are not likely to decay at the neck, leave the centre rather lower than the sides, so that the water shall not run away and leave the centre dry. For hard-wooded and delicate things, however, the soil should be level; always leave about half an inch below the rim to allow for watering.

Give the plant, or rather the soil, a good watering from a fine-rosed pot or syringe to make the surface firm, and use the same in preference to the spout in all waterings for some days till the soil has got settled. It is not advisable to keep on shifting plants into larger pots after they have attained a certain reasonable and movable size; a 5-in. or 6-in. pot, or what is known as a 48 or 32 size, is quite large enough for the majority of window plants. So when a plant reaches such a size and requires potting again, prepare one of the same size, turn the old ball out, and break or shake away nearly all the old soil, leaving just a little on the roots; if these are very long, shorten the strongest back considerably, leaving the short fibrous ones untouched. Put it into the new pot, spreading the roots out as evenly and naturally as possible, and working the fresh soil in and amongst them nicely; fill up and press firmly, then give a good watering. It is advisable, wherever possible, to shut up the plants pretty close in a frame or pit after this operation until they have recovered the check; at any rate put them in as quiet and shady a place as you have. If the plant has developed a large head, however, it is better to have pruned it back considerably before repotting. Harden the plants as much as possible by standing out of doors in a sunny place and giving only very little water for a time, then cut back pretty closely; put in a close and warm frame or house, or keep shaded and quiet, giving only very little water till the young shoots have broken, and when these are 1 in. or 1½ in. long repot as above. This should always be done in spring or summer.

Do not give newly-potted plants more water than just sufficient to keep the soil moist for some time until the roots have got well to the sides of the pot again, as if the new soil, before it is occupied by the roots, gets very wet or sodden, it is apt to sour, and then the roots will not like it or run freely in it, and the plant will become sickly.

The period at which plants require most water is when they are growing vigorously or flowering, or both; then they can scarcely have too much, especially if the weather is warm; but one rule must be always observed—never water a plant until it requires it, that is, when the soil is dry, or nearly so, though you need not wait until the plant flags. When the plant wants it, be it twice a day or once a month, give it a good soaking, and leave it alone till wanted again. Again, do not let plants stand in a saucer of water, but let all superfluous moisture run freely away. There are some exceptions to this, viz., Arum or Calla Lilies, Spiræas, Musk, and even Fuchsias when in full flower in hot weather require so frequent waterings, that it is better to let them stand, at least for a time, in a saucer of water and suck it up, as they will speedily do. But such a practice is almost certain death to any delicate-rooted plants, if frequently done, or continued for any length of time.



Window Garden with Climbers.

Never water plants with very cold water, but from October to May, at least for indoor plants use tepid water at a temperature of 60° to 65°. Manure water may be beneficially employed for plants that have become what is termed pot-bound, that is, the pots full of roots, when they need some extra nourishment. This may be made in several ways; put about a bushel of fresh horse or sheep droppings into a good-sized tub or barrel, fill up with water, add a handful of lime, and stir all up well, then let it settle till next day, and one part of this diluted with about two parts of water makes a capital stimulant. Never use it stronger than weak tea, and it should always be used in a clear state, not thick or muddy. The old rule for this, and a very good one it is, is "weak, clear, and often." Soot water, not too strong, made by beating up a spadeful of soot in a little water to a thick paste, and then diluted, may be used with advantage to virgin soil, but not to ordinary town soil; that is too sooty already. Or sulphate of ammonia dissolved in water in the proportion of about half an ounce to the gallon is very good for many things, especially Pelargoniums; it induces a plentiful bloom. Guano water, too, in the proportion of an ounce to the gallon, or rather weaker for delicate things, is useful.

If you wish to have good individual specimens, only grow a few plants and turn each round occasionally, so as to expose all parts to an equal share of light, and balance the growth, but if you aim at filling the window as full as possible, do not attempt this, but arrange your plants pretty closely, so as to contrast and look well, and never turn or move them, but let them "grow in" altogether, and produce a solid bank. We must confess we do not personally admire this style, but tastes differ, and it seems to please some people very well.

Where plants are grown in a room that is not much used, or in any case, indeed, the air must not be allowed to become stuffy or close from keeping the window too much closed; on the contrary, the internal air should be changed as often as possible, and to this end a little air should be given, *i.e.*, the window should be opened a little way for an hour or two at least every day, except in severe weather in winter. Such plants as Ferns, Begonias, &c., require comparatively little air, and should never be exposed to wind or a thorough draught. For all such things opening the window a few inches, more or less, at the top only on fine days for a few hours will in general suffice. Fuchsias require a more free supply of air than this, and Geraniums, Pelargoniums, Balsams, and others must have as much as possible whenever the weather is at all genial and the thermometer outside above 50° or 55°. It all cases it is far better to open the window-sash at the top than at the bottom.

One other hint. Never paint flower-pots, but keep all the pores as clean and open as possible, It is better to give your plants air at night and in the early morning when the weather is warm, as it is then far purer and more healthful than in the daytime, when so many fires are going. For the some reason we give more air on Saturday evenings, Sundays, and on to Monday mornings; also on general holidays. All these things make a difference, though it may be only a small one, but "many a mickle makes a muckle," so do not neglect one. B. C. K.

VEGETABLES.

Potato Growing.—I am interested in the Potato growing department of Gardening, and have noticed some remarks of "Burns" on the subject. His experience is on light soils with porous bottoms, so is mine, but with different results. I have not grown International or Woodstock Kidney, but from what I have seen of them this last season I should not care to invest in them. More than one grower I know has not his seed back again, but I certainly did set up Snowflake, and unless they do better than they have done these last two seasons, they will have to be a sort of the past, though a better cropper or handsomer shape I should not wish to possess; but I do not understand "B." saying his did not ripen till the last week in September. Were they true to name? My own were dug early in August, when nine-tenths were diseased afterwards, but the Schoolmaster, a later one, I shall go in for. I believe it to be the one for future growers. Magnums did well about here, and Champions too, but I object to their habit of making so much haulm, and so long before they are ready to dig. I see in Dec. 25 "Burns" takes "T. S." to task, and says the varieties are not to blame but the cultivator; and as he is curious to know the causes of failure, it is not that "T. S.'s" land is retentive of wet, or in good heart, or sick of Potatoes, nor saturated with smoke; the early sorts he enumerates were diseased generally about here; and knowing his land well I think he has nothing to complain of on the score

of situation or soil. For many years he has been a successful exhibitor at the shows.—MARKET GARDENER.

Potatoes during Frost.—In large vaults Potatoes are exposed to but a minimum of danger; it is when they are stored in ordinary heds, rooms, stables, and similar places that danger is to be apprehended, and where all possible precautions are necessary. Where there is a bulk of one sort the safest place for it is on the floor, and it should be kept in bounds by means of stout boards. For this the covering should in the first place be cloths, sacks, or any close-lying and air-excluding material, and upon this a thick covering of straw, the thickest portion being upon the crown of the heap, where a little moisture is likely to accumulate. If the bulk be dry, it is a great point in favour of the safety of the tubers. Smaller quantities may be well secured in bins, boxes, or tubs, but hampers should be avoided, and if some be stored on shelves, it is necessary to be as particular as to the nature of the floor on which they lie as upon the thickness of the covering. If in boxes or tubs, these should be placed close together, and should have some sacks or similar covering over them, and then a thick covering of straw. In all cases it is well to put some boards, slabs, or anything at hand upon the straw to make it lie close, and thus exclude as much air as possible. When a thaw takes place, three or four days at least should elapse ere the covering is removed, as should any little touch of frost have got admission, it will be productive of less damage if it be allowed to escape gradually.—A.

Trebon's Onion.—This variety was quite new to me last season, but, having obtained a packet of seed of it, it did so well, and proved such a real novelty, that it now must take a permanent place in my vegetable list. With ordinary garden culture the bulbs averaged 12 in. in circumference, many of them being 14 in. It is very handsome, not unlike, both in size and appearance, the imported Spanish Onions. In quality it is super-excellent, having the fullest Onion flavour, and it is deliciouly mild. Respecting the origination of it I know nothing other than that the name appears to imply that it is of French origin.—W. W.

Early Peas.—Now is the time to sow early kinds of Peas in turf or boxes. If these be placed in any house or pit, from which frost is excluded, and be planted out, when spring sets in they will furnish a crop which will supply the place of those which may have been lost through the severity of the weather.—S.

Asparagus in Borders, Shrubberies, and Waste Spaces.—Those who are in the least doubt about how to cultivate Asparagus by the new way or the old way may settle the question to some extent by putting single plants in mixed flower borders, thin beds of shrubs, or in open spaces in the ornamental garden. The Asparagus fairly grown is a very beautiful plant. For its foliage, it is well worth growing if it had no other value whatever; in fact, among the many hardy plants we have it is, perhaps, the most graceful, and it would no doubt long ago have been used as an ornamental plant if it had not been used in the kitchen garden. If the soil is of the usual quality of garden soils, a very little manure will suffice for planting. If it is very poor it ought to have some manure slightly dug in, but the old way of putting 2 ft. or more of manure under the plant is quite needless. There are hundreds of gardens in which a bit of good Asparagus is never seen, where good supplies could be obtained from plants or groups placed in the shrubs or borders. Certainly it is not the best way, but it is far better than the common and foolish one of having ten or twenty plants where one should be. March is the time to plant.—V.

THE following graphic portraiture of a too common but eternally profitless treadmill experience is credited to "a well-known Illinois writer": "The average Western farmer toils hard early and late, often depriving himself of needed rest and sleep—for what? To raise corn. For what? To feed hogs. For what? To get money with which to buy more land. For what? To raise more corn. For what? To feed more hogs. For what? To buy more land. And what does he want with more land? Why, he wishes to raise more corn—to feed more hogs—to buy more land—to raise more corn—to feed more hogs—and in this circle he moves until the Almighty stops his hoggish proceedings."

CAMPANULAS OR BELL-FLOWERS.

THESE constitute one of the most interesting families of hardy flowers, and some of the many beautiful species should find a place in every garden. A few of the kinds appear to be tolerably popular, but the majority of them are but rarely seen in gardens. The Campanulas vary more in manner of growth than in colour, and if they have a defect it is that they exhibit some little uniformity in this latter respect. It must, however, be said that the various shades of blue which distinguish the Bell-flowers are of a peculiarly soft and pleasing description, so that even when the showiest species amongst them are planted in masses the effect, though striking, is never overpoweringly brilliant. There is no more grand hardy flower than the Canterbury Bell when all attention has been paid to its culture. Seldom, however, is it that one sees this fine biennial in full perfection; yet when well grown few plants surpass it in beauty and effectiveness. The great point, and this is where many err, is to sow very early in the year, so that the plants get the advantage of a long season's growth, so that by the autumn they have developed into large, robust crowns of foliage, containing a vast amount of growing force, and certain to start away with rude vigour the following spring. It should also never be forgotten that it is not the number of specimens which render a garden gay and interesting, but rather their quality, individually, so that half-a-dozen well-grown plants will yield as great a mass of bloom as ten times that number where they have been stinted in the matter of both air, light, and nourishment. Not only will this be the case, but the individual blooms will be larger and finer, and that beauty of form which every plant possesses in a more or less degree will be shown to the best advantage when each plant stands to a certain extent free from its neighbour, and has been allowed a free, unchecked development during the growing season. Few plants resent overcrowding more than the Canterbury Bell, for, naturally assuming a shrubby, much-branched habit, it requires a considerable amount of space for lateral development, and utterly fails to yield the full measure of its beauty when cramped and confined for growing space. The seed should be sown in March, and if the young plants can be at once planted where they are to bloom so much the better. This is not, however, always practicable, and is not absolutely necessary. A free open sunny situation should be selected, and there the seedlings should be planted out as soon as they become large enough to handle, setting them at least 9 in. apart. Generous culture is essential, plenty of manure, and abundance of moisture at the roots being the great essentials in the culture of the Bell-flower. Somewhere during October the plants should be taken up and placed in the positions assigned to them, where the following summer they will make a grand show. The Canterbury Bell is by no means fastidious with respect to soil, but will thrive in anything between sand and stiff clay. At the same time, any little extra pains bestowed upon the preparation of the soil will not be thrown away, and the natural defects of the soil should be remedied as far as may lay in the power of the grower to do so. A very excellent species of Bell-flower is C. carpatica and its white variety, now much employed for bedding purposes, for which its neat, compact, and moderate growth admirably fits it. It grows freely in almost any situation, providing it is not too shaded, and, like the Canterbury Bell, thrives in most soils, preferring, however, a somewhat light, well-drained loam. The Carpathian Harebell is one of the most free-flowering species of the genus, and if afforded plenty of nourishment throughout the summer, watering occasionally in hot dry weather, and picking off the seed vessels as they form, will go on blooming through the greater portion of the summer months.

Campanula as a Pot Plant.

It is one of those hardy subjects which, like the Viola, may be used as an efficient substitute for tender bedding plants, and owners of small gardens who may not have the convenience for raising or wintering bedding plants would find in this little Harebell a useful auxiliary. It may easily be raised from seed, either sown in the open ground in April, or better still in March, in pans of light soil, placing them in a frame or cool house until the young plants are well above ground, when they should be gradually inured to full exposure, eventually planting them out in good free soil at a fair distance apart. Whoever has an established stool will find no difficulty in propagating this species, as by taking off young growing shoots with the whole of the stem attached and pricking them into free soil in a shady situation they will soon take root.

Another excellent dwarf kind is C. turbinata, which bears fine large, open, bell-shaped purple flowers, and which succeeds well in any free rich soil. This is really a handsome species, and deserves good cultural care. In C. pumila, the dwarf Harebell, we have a small growing species, forming flat carpet-like masses of bright green foliage, and bearing a number of flower-stems with one flower to each of them. It is a very manageable kind, and will grow well in almost any soil or situation. Another dimi-

nutive kind is found in C. pusilla, an extremely neat, fresh-looking plant with crowded, toothed, heart-shaped foliage, which, in the flowering season, is covered with bloom. The proper place for this species is some elevated position, such as a rockwork, where the roots are assured against stagnation and the plant generally against excess of moisture in any form, otherwise foliage is apt to die off in patches, thus disfiguring the plants to a serious extent. One of the handsomest members of this family is the noble Harebell (C. nobilis), the individual blooms of which are exceptionally beautiful, being long, large, creamy-white, and spotted with purple or crimson. It is a fine subject for any garden, and deserving of all cultural pains which may be expended on it. In very wet and cold localities, where the soil is liable to become sour and water-logged, it is apt to suffer in hard winters, but a little protection will suffice to make all safe. The Peach-leaved varieties should not be omitted from our present list, for they yield in refinement and beauty to no another known kind. The variety named coronata plena is notable for its perfectly double pure white flowers, which bear a striking resemblance to the Camellia both in shape and refinement, thus rendering them serviceable for even choice floral decorations. The dimensions attained by this plant are in accordance with the culture given and the nature of the soil, as sometimes when in the enjoyment of suitable conditions it attains a height of from 2 ft. to 3 ft., whereas in poor soils it rarely exceeds 1 ft. It delights in a good depth of free rich soil, and does not object to a little shade during the hottest months of the year. C. garganica is a pretty dwarf-growing variety, more fitted for rockwork than the level ground. The same may be said of fragilis and Elatines, two small growing, but pretty kinds. When these dwarf growing species are planted in the open border, the soil, if at all tenacious, should receive a good dressing of river sand or some such porous material, and some stones or pieces of brick should be sunk around the plant in such a manner that their upper surfaces rise somewhat above the level of the soil. In this manner the danger of stagnation at the roots will be much avoided, and there will be the great advantage of a more or less dry surface for the young and, in the case of these delicate species, tender growths to risk upon. Many of these diminutive Harebells are apt, when the surface soil is of a holding nature, to damp completely away in wet inclement winters, but if the above directions are followed, there will be but little danger of their suffering. These small-growing kinds are not greedy feeders, and if once well planted will thrive for years without further attention.

Byfleet. J. CORNHILL.

Rudbeckia Newmani.—This was a very gay bed during summer and autumn—too staring, perhaps, for the taste of some, but we like bright flowers. To make up for its autumn flowering, blue-branching Larkspur was planted alternately in the same bed and pegged down. Its fine foliage lightened up that of Rudbeckia, and it came early into flower. When both plants are in bloom they look well.

Diplacus or Shrubby Mimulus.—I find plants belonging to this section of the Mimulus family most useful for many purposes. They last long in bloom and are easily grown; they do well in a heated pit or cold greenhouse, in any place, in short, out of the way of frost. Give them water enough in winter to keep them from getting dust dry; in spring prune them and pot and grow them on, and during summer they will make good plants either for the conservatory or for house decoration. Cuttings struck in spring and grown on rapidly also make useful plants, and bloom well through the autumn months. One or two good kinds are Golden Pheasant, Gordon's Stella, and a sort known by the name of antarcticus. All these bloom well if planted out in spring in the open borders and taken up for winter decoration.—J.

Love-lies-bleeding for Harvest Decoration.—There are few plants that come in more usefully for this than Amarantus caudatus, or Love-lies-bleeding, and now is the time to get the seed, so that it may not be forgotten when the other annuals are raised. To secure a good supply of plants of it fit for the purpose, early, middle, and late sowings should be made. For our decorations last harvest the red sort only was used, but a judicious admixture of the white and red sorts might perhaps be made to produce a pleasing effect.—B. S.

ANSWERS TO QUERIES.

4074.—**Garden on the Clay.**—Any kind of soil or material of a light, porous description that you can add to the natural staple will serve to permanently improve it. Lime rubbish is an excellent material, as is also river sand, and if you can get a few loads of road scrapings, you will find that they will render the stiff mould more amenable to ordinary culture. In the case of a garden resting on strong clay every effort should be made to ensure superfluous moisture draining away. If drains can be sunk some 2 ft. deep and say 9 ft. apart they will ensure the well-being of many of the more tender-rooted subjects. In any case the subsoil should be loosened, which may be done with a four-tined fork, taking out a trench of the top soil, turning up the subsoil, then filling in with the next trench of surface mould, and so on until the whole of the ground is worked through. This will not only allow of the subsoil coming into a more friable and suitable condition for the roots to work into, but the disastrous effects of heavy rains will be in a great measure obviated. With respect to propagating, we would advise you to procure a little good loam, leaf-mould, and peat, with some white sand. Small quantities of all these may be procured from various firms who advertise such.—J. C.

4080.—**Treatment of Muscat of Alexandria Grapes.**—The cause of your Grapes being green instead of yellow at the close of the season was imperfect maturity. This Grape requires a longer season of growth and a higher average temperature than such kinds as the Hamburgh. Thus, in order to ensure the proper ripening of the berries, and to enable them to attain the size and colour indispensable to a perfect condition, fire-heat should be given from March onwards. An average temperature of 55° by day and 50° by night will suffice during that month, a rise of some 5° being given in April, to be increased to 70° to 75° by day and 60° to 65° by night when in flower. During the summer, should a genial season be experienced, the ordinary natural temperature will suffice to carry them along until early autumn, when a little fire-heat will generally be found necessary to finish them off. Plenty of air must be given all through the summer, but should, as often happens in our climate, a period of ungenial weather supervene, it will be better to make a little fire at night. The Muscat of Alexandria delights in a strong heat accompanied by a free circulation of air when in full growth, a due appreciation of which fact will much help the grower in his operations. Although plenty of air is to be given all through the summer, every effort should be made to economise the sun's rays and raise the natural temperature, for it is not only more economical to do so, but is more favourable to the well-being of the Vines than when opportunities for so doing are allowed to pass by, and much fire-heat is resorted to supply the more genial and vigour-imparting warmth of the sun. Give air early in the morning on fine days, gradually increasing the amount as the sun increases in power, and shut up and syringe as soon as it is safe to do so. In the early autumn, or rather towards the close of the summer when the berries commence to colour, be careful to admit every day a free circulation of air, or the beautiful amber tint so much admired in this Grape will be wanting. At the same time, should the weather prove at all inclement during any portion of that season of the year, raise the temperature to at least 70° by means of fire-heat, leaving on a chink of air at night. To obtain fine samples of Muscat of Alexandria the Vines should be at least 2½ ft. apart, 3 ft. being none too much; every leaf then gets the full advantage of light and air. The application of bones and manure is so far right, although we do not consider that the bones are of much value as a top-dressing. The plants will do no harm if frost is merely excluded, and not enough heat given to stimulate the Vines before their time.—J. C. B.

4027.—**Cyclamens in Windows.**—There is more than one cause for Cyclamen leaves shrivelling up. Want of water will of course cause them to perish, but what will be more difficult for the inexperienced to understand is that too much moisture at the root will produce exactly similar results. When it is, however, borne in mind that excess of moisture causes premature decay, it will be easy to conceive what disastrous effects a sour, soddened state of the soil must have upon the delicate feeders of such a tender-rooted plant as the Cyclamen. At one time I considered the Cyclamen as unfitted for window culture, but from what I have lately observed I have been induced to change my opinions on this subject. I do not find that the Cyclamen cares much to have a circulation of air around it in the winter time. It is a plant that is very sensitive to cutting winds or chilling draughts of any kind, but at the same time it cannot exist long in health in the confined atmosphere of a constantly heated apartment, as therein the leaves soon become drawn, and the plant generally so enfeebled, that it loses the power to throw up its blooms, which perish before they can emerge from the bud state. The proper place for this plant is a cool room, where, as is often the custom, a fire is lighted now and then just to air it and dry out damp. If the window is light and the aspect south or east, the plant should do well, and throw up its blooms strongly and freely. From time to time it is advisable to take the plant out and well syringe or sponge the foliage, at the same time exercising care that no water falls down into the heart of the plant, as a few drops will suffice to cause decay in the bloom-buds. Watering must be conducted with great care during the dead of the winter, and when the temperature is maintained at a low degree. The soil should be allowed to become almost dry, though by no means dust dry, and sufficient water is to be given to thoroughly moisten the ball of soil. Plants in windows should always stand in a saucer, and water enough should be given to cause some of it to pass off through the drainage hole, the which must be emptied away immediately. On the return of bright days more water must be given, and the foliage should never be allowed to droop for want of it. Generally speaking, Cyclamens are potted in too holding a compost, and that is one reason why the roots are apt, when the plant comes into the hands of an inexperienced person, to suffer. The compost should be light and well sanded, so that it cannot come into a sour, close condition.—C. B.

4070.—**Worms in Pots.**—Your best plan in dealing with worms in the soil of your Tree Fern will be to get some fresh lime and make a solution of lime water; say about a quart of lime to a gallon of water. Stir it well and let it stand for a few hours until the water is quite clear, then pour off into a water-pot, and give to the ball in which the worms are. This should be repeated two or three times, as in such a large ball it may not be possible to kill all the worms in one watering. Many of the worms may be taken out when the Fern is repotted, but perhaps not all; therefore it is well to apply the lime water first.

4072.—**Cineraria Leaves Curling.**—Although there are some kinds of Cinerarias the leaves of which curl naturally, yet it is most probable that yours do so from some other cause. Are they kept too dry at the root? Turn one that is much affected out and see in the first place. Perhaps the atmosphere of the house is too close and dry. We certainly think that one or other of these things must affect your plants, and if this is so you can easily alter them, and either give the plants more water if needed, or keep the atmosphere of the house less dry.—A. D.

4075.—**Pruning Clematis.**—Clematis Lawsoniana belongs to the autumn-blooming or Jackmani group of the family, and the rule in their case is to cut back every winter the growth of the previous summer to within 12 in. of the ground. It may be that in your case this sort of treatment induces late breaking, and, perhaps, it would be best to cut back to about 4 ft. Usually the upper buds push earliest, and, therefore, if these are left the new growth and

bloom will be earlier. This course if followed will be at the expense of the bottom of the plant, which will soon get bare.—A.

4076.—**Tropæolum speciosum.**—You can get seed of Tropæolum speciosum from Messrs. James Carter & Co., seedsmen, High Holborn, and perhaps of most others, at 1s. or 1s. 6d. per packet. Tubers can be had from Messrs. James Backhouse, nurserymen, of York, or Mr. Ware, Tottenham. Seed if obtained should be sown in April under glass and in a gentle warmth, and when the seedlings are strong enough shift into small pots. From these they may be turned out into the open ground. A situation that is warm, but not too much exposed to the burning sun, and deep loamy soil suit best.—A. D.

4059.—**Liquid Manure.**—We have ever found one of the best of all liquid manure to be made with fresh horse droppings without straw saved in a stable. These should be put loosely into a coarse sack or canvas bag, tied, and put into a tub—say one bushel of droppings to ten gallons of water. Give the bag a turn now and then to ensure that the droppings are thoroughly saturated. The liquid will be ready for use after three days' soaking. By adopting this plan the liquid is always clear and free from impurities, and may be employed by a lady without difficulty, and will leave behind no unpleasant smell. A fresh bushel of manure may be added every week if necessary, but so much would hardly be needed with only a small house of plants.

4069.—**Warming and Ventilating.**—There is at present no plan of heating glass-houses so good as hot water heated in a boiler of some kind by ordinary fuel. Whatever the form of boiler may be, it should be large enough to do its work without much pressure even in severe weather, and there should be pipes enough in the house to warm the atmosphere sufficiently without themselves becoming unreasonably hot. These two items should always be insisted on, for there can be no real economy without. I am persuaded in most of the glasshouses in the country this matter does not receive the attention it deserves. I dare say most of the boilers made have some good quality if carefully set, and some years ago I knew an amateur gardener who had no boiler at all in the ordinary sense of the word, but simply a coil of pipes built in a furnace which he put together himself, and which he said answered well. As regards ventilation, I think there should always be the means of admitting air low down close to the ground line, and let it expand and rise as it becomes heated.—E. H.

4058.—**Azaleas Dying.**—Some people are successful in growing Azaleas under the conditions named by your correspondent "Perplexity;" at the same time many fail, or else the many thousands of plants annually imported would not find purchasers. One error often committed is in setting the plants outside in spring. As soon as they have done flowering there seems a desire to get rid of them, but they will not flower well if treated so, because the wood will not ripen. After they have done flowering, the seeds should be picked off and the plants be grouped together at the warmest end of the house, where if possible they can be kept a little closer, and have plenty of moisture in the atmosphere to encourage growth and be syringed with soft water twice daily; in short, maintain the condition that is found most suitable for growth. Any potting that may be necessary should be done at the beginning of the growing season, giving only small shifts, or else the growths may break away too strong. Then, when the growth is finished, give more air to consolidate the wood, and about the end of July or the beginning of August set the plants out on a bed of ashes in the open air in a partially shaded position. One of the causes why Azaleas die is irregularity in supplying them with water. The roots are fine, like hairs, and if the plants are once permitted to become dust dry, these hair-like roots perish, the leaves drop off, and ultimately the plant dies, though it may be months after, and the neglect the plant has suffered from may have gone from the mind. Though these fine rooted plants often die through drought, yet, on the other hand, a good many are killed by kindness, by overdoing it. It requires watchful care to grow Azaleas well; when that is given and their wants are understood they will grow freely enough.—E. H.

4079.—**Hoof Parings as Manure for Vines.**—We have no experience of this material in the culture of Vines, but have used them for most kinds of soft-wooded plants, but we must admit with but little appearance of benefit to the plants in question. Some years ago they were strongly recommended to us for such free rooted subjects as Geraniums and Fuchsias, and we were told to use them in the form of drainage, much in the same way as bones are commonly employed. We did so, and found that not only did they not do what they should have done, and nourished the plant, but they actually proved injurious to it. So far from the roots rushing greedily into the food thus prepared for them, no sooner did the first roots touch it than they decayed, in many instances becoming covered with fungus which the parings bred in any quantity; since that time we have declined to have anything more to do with hoof parings. Possibly, if they were submitted to some previous preparation, they might be employed with benefit. Perhaps some readers of GARDENING may have had more extensive experience of this material, and would give us the benefit of it. We should certainly prefer crushed bones for pot Vines.—J. C. B.

4064.—**Cutting Back Vines.**—As the Vines in question are, we presume, well established, we do not perceive any good cause for cutting them back to any great extent. We would shorten them to about three-fourths of their length in the case of the strongest canes, whilst the weaker ones might be cut in somewhat harder. We would not leave more than two canes to each Vine, and would cut the remainder quite away. If there are no plants in the house, and the Grapes are not required before the autumn, we would keep the Vines quite cool, allowing them to start naturally, and assisting them then when the state of the weather necessitates so doing. If the object is to fruit them at an early period 50° will be enough for the first month by night, rising to 55° in the daytime.—C.

4071.—**Iris anglica.**—I. angelica, xiphoides, or English Iris, and its congener, the Spanish Iris (I. xiphium) are quite hardy, but being at rest for a much shorter period than most bulbs, they must be planted early—not later than October. The best chance with them now is to plant in pots in light soil, such as a mixture of light loam, sand, and leaf-mould or peat, just deep enough to let the tips of the bulbs to be seen; place them in a temperature of about 50°, and keep rather dry until they show signs of springing. They are not likely to bloom the first year.—J. D.

4043.—**Syringing with Soot-water.**—If employed in a perfectly filtered state, soot-water will not discolour the foliage, and at the same time it will impart to it a very deep glossy hue. One of our largest and most successful Camellia growers makes a practice of syringing his large specimens with soot-water throughout the growing season, and strongly urges its constant employment. Soot, as is well known, contains a large percentage of ammonia, and it would appear, when outwardly applied, vegetation has the power of assimilating a portion of it, hence the deep colour which the foliage assumes. One of our large Rose growers, being much troubled with mildew, dusted a portion of his plants thickly with pure soot, which had the effect of destroying that pest, and the portion of the plantation thus treated was afterwards much greener than the general stock. The soot should be tied up in a not too coarse canvas bag, and sunk to the bottom of the tub, allowing the ammoniacal properties to escape as they can. Thus prepared, the foliage will not be stained when used for syringing, and I may add that this is the only right way to prepare soot-water for watering. It should be at all times transparent and free from scum.—J. C. B.

4068.—**Gros Colmar Grape.**—This is a variety which does not give much satisfaction when accorded the treatment considered proper for such a kind as the Black Hamburgh. It should be started early into growth, the beginning of March being none too soon, and requires in ordinary seasons the assistance of fire-heat to ripen it off as well as to mature the wood, which demands more heat to ripen off than that of most kinds. The extra care and expense involved in the culture of this Grape are then repaid by its superior keeping properties, as when well grown there is no difficulty in maintaining it in first-rate order until early spring. This Grape is a fit companion for the Muscat of Alexandria, both demanding a considerable amount of space, plenty of heat, air, and light from the time that they come into flower. For early work it has no value, the Hamburgh being much superior to it, and coming much sooner into fruit. It is simply a first-class late Grape, of high keeping qualities, and of noble appearance. It will certainly succeed grafted on the Black Hamburgh, and this operation may, if so desired, be reversed. We think, however, that in a general way such kinds as the Gros Colmar are not suitable for small growers; we never recommend them, as they demand much skill and more accommodation than can generally be accorded them.—J. C. B.

4055.—**Propagating Variegated Hollies.**—Propagating the variegated varieties of the Holly by cuttings is but seldom resorted to, in the first place because grafting or budding is more expeditious; secondly, because when worked on the type they grow away more freely and make reliable plants in less time. Formerly grafting was the almost universal method of increasing the variegated kinds, February being the time preferred for carrying out this operation. The stocks are to be two years old, and are headed back and whip-grafted. Of late, however, budding has been preferred, and has much to recommend it as being more easily and expeditiously performed. The best time for budding the Holly is in August. The buds should be inserted in the usual manner as near the ground as possible, the stock being left entire until the following March, when it will be seen by the inserted buds being plump or otherwise whether they have taken or not. Those that have taken should be headed back close to the bud, and the failures remain untouched, to be operated on again at the proper time. Cuttings will strike fairly well if inserted in the month of September in free sandy soil, making the soil very firm around them and protecting them from excessive cold and wet. The best place for them is a frame in a north aspect, where they may be cool and shaded during the spring and early summer months. Take care to keep them moist until rooted.—J. C.

4065.—**Grafting Old Fruit Trees.**—Cleft grafting and crown grafting are the methods usually employed in the case of old fruit trees. In the first place the grafts should be at once taken off and laid in in a dry, warm border, and covered up in frosty weather. Only the last year's wood should be taken, choosing such shoots as are free and strong. Cleft grafting is practised when branches from 2 in. to 3 in. in diameter have to be operated upon, and the proper way to go to work is as follows: Head off the branches, with a saw if you like, but pare the surface clean and even with a very sharp knife. Then cut away a portion of the stocks in a sloping manner, so as the crown of the stock may not be more than ½ in. broad. This done, prepare the graft in the following manner: First cut the grafts into lengths of about 6 in. to 8 in. with several buds to each. Then pare away the bark and some of the wood in a sloping manner about 2i n. in length on two sides, making it to have a wedge-like shape. The next thing is to make a cleft in the stock by means of a sharp knife, striking it down with a mallet, making the cut crosswise of the crown of the stock. Wedge the cleft open with some blunt instrument, and insert the graft, rind of course outwards. A variation of this method, and one now much practised, is to leave the stock entire, simply making a cleft in it and inserting a scion on each side, thus giving a double chance of success. Crown grafting is employed when the tree is headed down to the large branches, and is much practised in the case of old trees of which it is desired to change the variety. Cleft grafting may be practised from the middle of February, but crown grafting cannot well be performed until April, when the sap begins to run freely. Commence by paring off the top of the stock quite smooth and level; then prepare the grafts by cutting one side flat and a little sloping about

2 in. in length, making a kind of shoulder at the top of the cut to rest on the head of the stock. Then slit the bark from the top downwards quite to the firm wood, and, opening the rind a little with some wedge-like instrument, introduce it in such a manner as to separate the bark from the wood, and to allow of passing in the graft, the rind of which should be pared off on the side opposite to that which was cut as directed. The advantage of this system of grafting is that a number of grafts may be inserted on one branch, thus clothing the tree in a short time. The clay used should be well wrought, and in applying it bring it well round the grafts, placing quite 1 in. in the crown, and rounding it off a little so as to throw off wet, which if admitted would prevent the grafts uniting with the stock. By the end of May or beginning of June the grafts will have taken, when the clay and bandages should be removed, but a little fresh clay should be placed on the crown of the stock. Grafts inserted by this method generally succeed and go away strongly, but during the first two or three years of growth they are liable to be blown away by high winds, to obviate which a stick should be tied firmly to the old wood, fastening the graft to that.—B.

4073.—**Coal-ashes for Garden Paths.**—We think that your best way would be to lay the ashes on the gravel, not mixing the two materials. Coal-ashes are excellent for kitchen garden paths, as they allow of killing the weeds with the hoe, which cannot well be done where gravel is employed. We would loosen the gravel a little, and place a layer of at least 4 in. of ashes thereon. Weeds will still come, although not in such quantity, and they may be easily hoed up.—J. C.

4060.—**Ampelopsis Veitchi.**—It is most probable that there is objection to the tendrils of your Ampelopsis attaching to an outdoor wall, because the material does not attract, or it may be that it is too cold, or perhaps too dry. The fact that the tendrils attach themselves freely in a greenhouse shows that the plant likes the shelter and probably the moister condition of the wall. We can offer no other explanation.—A. D.

4063.—**Berried Iris.**—Seeds of the Gladwin Iris will grow if they are new and good. Sow in pots of sandy soil in March, placing the pots in the warm frame, gradually hardening them off when the young plants appear. It would be as well to leave them in the pots the first year, planting them out the following spring in a prepared nursery bed.—E. H.

4071.—**Iris anglica.**—English Irises are quite hardy. Plant as soon as the weather is suitable. It is not absolutely necessary to take them up every year. Many of them may be planted in the wild garden and naturalised.—E. H.

4065.—**Grafting Old Fruit Trees.**—Having been pretty successful in grafting on Crab stocks from the woods, I shall be pleased to help "J. T." if he will send me name and address in full. I have plenty of scions of good sorts, both Apple and Pear, and could send two pieces joined in the required manner for illustration.—E. M., *The Croft, Wallingford, Berks.*

4067.—**Liliastrum Anthericum** (St. Bruno's Lily).—This is figured in the "Botanical Magazine," t. 318, root and flowers, and Mr. Grindon's description of "star-like flowers" is fully borne out by the plate, which properly represents the flower as a six-rayed star when fully expanded. The root consists of many more rootlets than four points, which is, I think, what a star-fish possesses.—SOL.

4063.—**Sowing the Gladwin Iris.**—I grow the Gladwin Iris on banks around my garden for the berries in winter, which after the beauty is over I throw on some spare place among shrubs, &c., and always find a quantity of young plants spring up.—GANG FORWARD.

4050.—**Paint on Glass.**—If "Greenhouse" will make a strong solution of common soda with hot water, by its aid he will quickly get off the paint from his glass; indeed, it will fetch paint off anything. Use it hot.—J. W. T.

4113.—**Varieties of Leeks.**—*Forget-me-not.*—You can get seed of any of the varieties of Leek you want from any of the seedsmen who advertise in our columns.

4114.—**Iris iberica.**—I have recently purchased and potted some bulbs of Iris iberica, but cannot find any mention of the plant as a garden Iris in any book I have. Iris iberica should be the Latin name for the Spanish Iris; but of course it is not Iris Xiphium, but seems to be tuberous-rooted. I find in an old book Iris sibirica (the Siberian Iris) recommended as a good hardy, early-flowering species, and as the names of garden plants, especially if difficult to pronounce, "tend ever toward corruption," and as Iris sibirica becomes Iris iberica unless pronounced with the greatest deliberation, I thought the two names might belong to the same plant. Can you solve my difficulty?—J. D. [Iris iberica (the Iberian Iris—Oncocychis ibericus) has only been introduced to gardens a few years. It is a remarkably striking kind, reminding one of I. susiana. It flowers in summer, and requires a good sandy soil. Iris sibirica (Siberian Iris) is totally distinct from the foregoing, and thrives well in the worst clay soils, in which other kinds would perish.]

4115.—**Forwarding Onions and Leeks.**—*G. H. D.*—If you can make up a little heap of manure, which will give a little heat, on which to sow your seed, you will gain time. Put 2 in. or 3 in. of fine light soil on the manure, then place your frame on and sow the seed. If preferred, the seed may be sown in pans or boxes, and placed on the manure.

4116.—**Passion-flower Dying.**—*Robin Hood.*—What do you mean by a greenhouse heated by a fire? If the fire is in the greenhouse no wonder the plant is dying. We cannot name from a dead leaf.

4117.—**Arum Lilies in Water.**—Having read "T. W.'s" account of growing Arum Lilies in water in the open air in GARDENING, Jan. 8, I should be glad to know if I could grow them in the way he describes in a small London greenhouse, kept in the winter at about 45°. Should the experiment be worth trying, what depth of water should the pots be kept in?—P. P. [They would grow perfectly if they got plenty of light. The surface of the pots may be 1 in. or 2 in. under the water.]

4118.—**Asters and Silenes.**—These are annuals, and to flower in July the Silenes should be sown early in March in the open ground, but the Asters must be sown at once in boxes or pots in a warm frame or house, and be pricked off and finally planted out in May.

Weekly Subscriber.—Your question is an advertisement, and as you neither send us name nor address we cannot answer you further.

Wandering Jew.—*Leek.*—Saxifraga sarmentosa.

Bug in Apple Trees.—*Godolphin.*—Paint the affected parts with paraffin oil or Gishurst Compound.

J. E.—We know of no good book on the subject.

Names of Plants.—*Conifers.*—1. Abies balsamea; 2, Thuja orientalis var.; 3, Thuja Wareana; 4, Picea Nordmanniana; 5, Pinus Cembra; 6, Pinus Strobus.—*W. L. S.*—Sedum monstrosum (a hardy plant).—*A. McC.*—Apparently a wild Raspberry of some kind; we cannot name without seeing the bush or fruit of it.

QUERIES.

4119.—**Quick-growing Ivy.**—I wish to cover an unsightly doorway in a garden wall with an arch of creepers. Could anyone kindly tell me the best and fastest-growing Ivy, and what Clematis or other flowering creeper will best grow with the Ivy?—T.

4120.—**Cobæa scandens.**—When does this flower? and is the flower a showy one? Ought this plant be much stopped or cut back?—ERIN.

4121.—**Orchids for Cool Houses.**—Will anyone kindly give a list of twelve best Orchids for cool house, those preferred that will grow on tiles, old wood, &c.? also any directions as to temperature required for them?—ERIN.

4122.—**Tropæolum speciosum.**—Does this die down in winter? and will it grow trained to wire?—ERIN.

4123.—**Slugs and Ferns.**—Having planted Ferns beneath a stand in the greenhouse, I am much annoyed by slugs. Would lime or strong soot thrown round the Ferns injure them? and would it have any permanent effect in ridding the ground of slugs?—ERIN.

4124.—**Lapageria rosea.**—When does Lapageria rosea throw shoots? and growing what is the best time for moving this plant?—ERIN.

4125.—**Cure for Thrips.**—Will some one kindly tell me of a good remedy for thrips? I have several plants, such as Myrtles, Fuchsias, &c., infested with them. Also is nicotine soap good to wash Vine rods.—NOVICE.

4126.—**Improving a Grass Plot.**—I have a Grass plot which I wish to have done up to look beautiful in summer, and be nice to walk upon. Will some reader inform me what I should do, as it looks like a pasture, and is coarse and knotty, the Grass growing in some places 1 ft. high, like a wilderness, and other places nearly bare. The turves were laid at first from a field where building was going on. I am not able to roll it, as I cannot get a roller through the garden gate. Would it be best to sow fresh seeds? and what quantity will be required?—ONE WHO WISHES TO KNOW.

4127.—**Keeping Tomatoes.**—Can anyone tell me if I could possibly keep Tomatoes in good condition until next April? and also the best way to do so?—ARTHUR.

4128.—**Paris Daisies not Flowering.**—Can anyone tell me why my yellow Daisies, Etoile d'Or, have never flowered since being brought in and cut down in October? They have been in gentle heat, and have made strong growth, but all the buds that appear turn brown and die off at once.—L. M. D.

4129.—**Planting Potatoes.**—Will any correspondent answer me the following? I have about ½ an acre of land under Grass. Will it be wise to plant it with Potatoes if ploughed as soon as the frost is gone? and shall I use much manure? and about what quantity of Potatoes would it take to crop it?—R. FRUNCE.

4130.—**Liming Garden Walls.**—I am about to lime my garden walls, which are covered with fruit trees. Will it injure the plants if they get coloured with lime through doing the walls, which they are nailed against?—A TOOL.

4131.—**Nicotiana longiflora.**—I was in hopes that some one would have answered an inquiry of "An Old Salt" in GARDENING of the 8th inst. as to how this plant should be treated. I bought a plant, as did "An Old Salt," and my plant must be own brother to those he describes, as I cannot keep a leaf upon it, and have tried it in several houses. I wish some would give us a hint as to how this "fragrant plant" should be cultivated. To show I am not a confirmed grumbler, I tried the plan, suggested by a correspondent some time ago, of striking Rose cuttings in a bottle of water kept pure by a small piece of charcoal. I have succeeded admirably; the cuttings rooted well. They have been planted in small pots in a light soil, and are now coming into bloom. The cuttings taken at the same time and treated in the ordinary manner are not so forward or so healthy in appearance.—SOPHIA CHRISTY.

4132.—**Mice and Crocuses.**—Can any reader inform me what is the best way to stop the ravages of field mice which are eating my Crocus bulbs in the ground? They do not molest the Hyacinths or Tulips, but will soon have cleared off all my Crocuses.—T. P. Y.

4133.—**Covering Greenhouse Walls.**—I have a lean-to greenhouse; it was erected about three months ago. Can any one tell me what creeping plants would look well and quickly cover them? I tried a Maréchal Niel Rose, but the green fly spoiled it. The wall, which is behind the plant stand, does not get much sun.—PERPLEXITY.

4134.—**Flag Iris.**—I have several plants of the common Flag Iris, which produces a great number of flowers, but only one or two on each stem come to perfection. Those low down the stems do not open; what is the cause?—LEWISHAM.

4135.—**White Primula in Windows.**—I have a white Primula bought last year; it has bloomed almost ever since. We divided the roots in October, and it has not done well. Will some one kindly tell me what soil I ought to use? and if the air of the sitting-room is too warm for it? The fire goes out after 10 p.m.—A NOVICE.

4136.—**Liming Cropped Ground.**—I have a large bed of Turnips; also a bed of Parsnips. Will it hurt either crop if I apply lime to them now? or had I better wait till they are off the ground? The ground I intend for Potatoes I shall feel much obliged if some one will give me the information.—C. B.

4137.—**Treatment of Unhealthy Plants.**—The latter end of March last I took to a small greenhouse, the plants in which were in a very bad state; some of them I saved, amongst them several Camellias, some of which made growth, and others did not. Those that made growth formed buds, but they have all dropped, and some of them are very straggling and bare in the middle. How had I better treat them? I think they are over-potted, so I wish to know if I should repot them and cut them in now or wait till March, as they seem to be pushing for new growth?—R. L.

4138.—**How to make Pelargoniums Flower.**—I have got a dozen good strong plants of Pelargonium in 3-in. pots; they were put in as cuttings last August. I should be glad if some one would let me know what to do to get them to flower next summer, and what sort of soil they should be put in, and when ought they to be repotted.—J. W.

4139.—**Plants for Shady Garden.**—Our house is E. and W., and the garden much built in. The garden is small, but I have by manuring it got beautiful soil, and am anxious to have some nice plants, but we get very little sun (on one side especially), and I shall feel much obliged if some one will tell me which of the following plants will grow best in the shade: Evergreen Thorn, Passion-flower, Clematis Jackmani, Wistaria, Cotoneaster microphylla, Banksian Rose, Moss Rose, Sweet Brier. I want some of these to grow in a box on the balcony and to droop over the rails. Would the Cotoneaster and Wistaria or Passion-flower do? I also want something over the hens' house (very little sun), and some on the far wall, which is very high. I thought they would be protected and warm there. Would the Evergreen Thorn grow on the hens' house over the wood part? the run is covered with wire. Also is it true that Sweet Brier kills other things? or could I plant a Clematis or Rose beside a hedge of it?—BEE

4140.—**Frozen Potatoes.**—Can any one inform me whether frozen Potatoes (sweetened only) are worse for planting? Also what is the cause of Onions rotting? A large percentage of mine rotted this last season, though they were harvested in the best possible manner.—BODFARIAN.

4141.—**Frozen Plants.**—I have an old Grape house very imperfectly heated. I have a lot of Geraniums, mixed kinds, and Fuchsias, old plants and cuttings taken in the autumn. They have done very well till this severe frost came, which I am afraid has killed many; the leaves of the Geraniums have turned all colours but green, and hang down; the stems and branches feel soft and hollow, although the young wood at the ends are still green in some. How shall I treat them? and is there any prospect of preserving any of them?—W. C. W.

4142.—**Hardy Aquatic Plants.**—Will some one kindly name a few good hardy aquatic plants for growing out-of-doors in Lancashire?—W. R.

4143.—**Covering Back Wall of Greenhouse.**—I built a greenhouse, the back wall of which is about 9 ft. high and 13 ft. long. The house is heated by a brick flue running all round, the temperature never rising much above 45°, and is sometimes as low as 38°. The back wall being perfectly bare, I would like it covered with some climber or anything else more suitable. What would be best for such a purpose? Would a Vine or Fig tree be suitable? Also what other plants besides Geraniums and Fuchsias could I grow with success next summer?—GREENHORN.

4144.—**Primulas Failing.**—I have a number of Chinese Primulas which I grew in cold frames last summer. I housed them about the end of September, and they grew and bloomed well until a month ago, when they began to look sickly. The first thing I noticed was the ends of the leaves turning soft, then the flowers began to drop, and now some of them look like rags. On examination I find the base of the leaf-stem (where it joins the main stem of the plant) to be quite rotten in some cases; in others it is still sound. What is the cause of this? and how can I remedy it? I am not aware that I have over-watered the plants, but have watered when almost dry.—SUBSCRIBER.

4145.—**Building and Stocking a Fernery.**—I am about to cover in a corner to form a Fernery. Can any reader recommend a system of glazing in which putty is not required, and is it expensive? Also, which is the best work on Ferns? I want one with plates, which will enable one to identify the different sorts.—HARRY ELLIS.

4146.—**Plum Tree, how to Manage.**—I have a sucker from an old Plum tree; it stands 12 ft. from the ground; there are twelve branches. The old tree has been dead two years; will it require grafting or budding? or will it bear fruit without either? The fruit of the old one was a very large dark brown Plum. A few hints what I had better do with it will oblige.—C. B.

4147.—**Hyacinths Coming into Bloom.**—Will some one be kind enough to tell me whether Hyacinths coming into bloom require the water to be changed? and what to do do with them after they have bloomed?—C. B.

4148.—**Heating a Greenhouse.**—I am building small span-roofed greenhouse about 15 ft. long. Ca any reader tell me from personal experience whether can successfully heat it with gas so as to produce sat factory results?—BECKENHAM.

ABUTILONS.

THESE are among the most useful of plants for small greenhouses or windows. They are of easy culture, free from attacks of insects, and the variety of their blossoms is now so great that almost any desired colour may be had. For winter flowering, some of the Abutilons are especially useful, the white-flowered kind, called Boule de Neige being the one most preferred for this purpose. The blooms of this are largely used in bouquets during winter. The stamens, which are furnished with yellow anthers, are nipped out with finger and thumb, and the petals are care fully turned back, which gives the flower the appearance of a beautiful white Convolvulus. During summer Abutilons are largely used in flower gardens, and good standard plants of them are very effective. When used in this way, too, they serve two purposes. They make good growth, and form a feature in the flower garden during summer, and if they are lifted and potted before frost comes, and placed in a warm greenhouse, they will give abundance of flowers during the winter. Small plants are, however, the most useful for windows and greenhouses, and they may easily be procured from cuttings struck in sandy soil in a warm frame or greenhouse (or even in a window if a bell-glass can be placed over them) during the spring or summer months. For winter flowering it is a good plan to strike a few cuttings during June or July, pot them on till 6-in. pots are reached, and keep the shoots pinched back to make them bushy. They may be plunged out-of-doors till September, when they may be housed, and if a little manure-water or a top-dressing of some artificial manure be given them occasionally they will continue in flower all the winter and spring. The variegated-leaved kinds are well worth growing for their foliage alone. Such kinds as A. Darwini tessellatum make excellent plants for small vases for room decoration. Some of the more vigorous-growing kinds are also well adapted for covering greenhouse walls. Thus situated, they keep on growing and flowering all the year round, provided they are planted in good loamy soil and are supplied with a little liquid manure occasionally. A. vexillarium and A. insigne make excellent plants for training up rafters or pillars in conservatories, the latter kind yielding in winter abundance of purplish-crimson blossoms. Abutilons may be easily raised from seed, which is a good plan when a number and a variety of plants are required. The seed may be purchased at any good seed house or nursery, and if sown in March or April in a pan of sandy, well-drained soil in a gentle heat it will quickly germinate, and the plants if potted on will grow rapidly, and when allowed to get pot-bound flower abundantly. When standard plants of the small-growing kinds, such as vexillarium, are required, they are grafted on stocks of robust kinds, and thus good heads are quickly formed. When the plants get too large for the window or greenhouse, put in a few cuttings and plant the old plants out in the open air and let them take their chance, or throw them away, as young plants are always the most useful and manageable. Among the best kinds may be mentioned the following, which we have extracted from a report by Mr. A. F. Barron in the *Journal of the Royal Horticultural Society* :—

GROUP OF ABUTILONS.

ANNA CROZY.—Plant of robust, vigorous growth; fine habit; flowering freely late in the season; good for winter flowering. Leaves large, broad. Flowers large, and of finely-cupped form; pale lilac, with dark veinings. Very pretty.

ALPHONSE KARR.—Plant of tall, free growth, and fine branching habit. Leaves small, deeply cut. Flowers small, of fine rounded form, borne on long slender stalks; colour reddish-orange, with dark veinings. Free flowering.

BERANGER.—Plant of tall, erect habit of growth; not branching. Leaves large, deeply cut. Flowers very large and elongated, of a clear pale orange colour, beautifully streaked with dark brown. Very showy, but somewhat shy flowering.

BOULE DE NEIGE.—Plant of fine free-branching habit. Leaves of medium size, somewhat pointed. Flowers of medium size, of finely-cupped form; pure white. Very free flowering. Excellent.

DARWINI GRANDIFLORUM.—Plant of fine habit. Leaves large. Flowers very large, of longish form, of a pale orange colour, with dark veins. Free flowering and good.

DARWINI ROBUSTUM.—Plant of fine, compact habit. Free flowering. Flowers orange, shaded with rose; of fine form. Distinct and good.

DARWINI TESSELLATUM.—Plant of fine, robust habit. Very free flowering. Flowers bright orange, similar to Darwini. Leaves large, broad; beautifully variegated or marbled; light green and yellow. Very ornamental, whether in or out of flower.

Louis Marignac.—Plant of fine habit. Very free flowering. Flowers large, of finely-rounded cupped form; clear pale lilac colour, with slight venations. Very pretty. One of the best.

Louis Van Houtte. — Plant of compact habit of growth. Free flowering. Flowers large, of fine cupped form, but somewhat rough; dark purple colour, with white throat. Distinct and beautiful.

Megapotamicum.—Plant of slender, spreading habit. Leaves small and pointed. Flowers small, bell-shaped, and singularly beautiful, the calyx being dark red, the corolla pale yellow, and the stamens dark brown, in very pleasing contrast.

Megapotamicum variegatum.—A variegated leaved form of the preceding.

Niveum marmoratum.—Plant of free growth. Leaves large, broad, downy, beautifully marbled pale green and yellow. Flowers of medium size and loose form; yellow, streaked with dark orange. Valuable as a handsome foliage plant, and very suitable for bedding.

Perle d'Or.—Fine dwarf-growing habit. Free flowering. Flowers of fine, rounded, cupped form; of a pale Primrose colour. Very pretty. A good variety.

Insigne (syn. igneum).—Plant of tall, free growth. Leaves large, heart-shaped; very thick and rugose; deep green; stem covered with short brown hairs. Flowers borne on long and slender panicles; the petals short, broad, much reflexed, of a dark purplish-crimson colour, with dark venations. A late autumn or winter-flowering species. Very distinct and beautiful.

Le Grelot.—Plant of fine, compact habit. Free flowering. Flowers large, and rather long; finely cupped; of a pale rose colour, with dark venation. A very beautiful variety.

Lemoinei.—Plant of fine, free habit. Leaves large, somewhat pointed and toothed. Free flowering. Flowers large; pale yellow; of finely cupped form; borne on short stalks. A very fine variety.

Sizes of Propagating Pots.—Opinions differ as to the sizes of pots best suited for striking cuttings in; some think 3-in. ones best, others 6-in. ones. My own opinion is that size is of little consequence; some do best potted singly at first, and then the roots do not get broken in potting, as they can be transferred from one pot to another without injury in any way, a point of great importance in the case of brittle-rooted plants. My intention now, however, is to point out to the inexperienced the way in which 8-in. pots may be used to the best advantage; I prefer them, in fact, to either 6-in. or 7-in. pots. In the case of 8-in. pots, instead of putting crocks in them in the usual way, take a small thumb or other pot, according to depth (as they differ in that respect from most potteries), and invert this upside down in the large one; then fill all round it to just above its top with small crocks; on this put some rough material to keep the drainage open, and then fill up with soil in the usual manner. In this way I found uttings to strike as quickly and as well in the centre as round the sides of the pots; the inverted pot forms, as it were, a chamber by means of which the bottom heat is equally distributed all over the pot, and the soil does not remain wet so long in the middle as it otherwise would, causing the cuttings to damp off, especially such as Verbenas and those of a similar character I have found pots crocked in the way just recorded useful for starting such plants as Alternantheras, Coleuses, &c. I put the pots in evaporating troughs and keep them filled with water; here cuttings of such plants strike in a very short time.—C. F.

Japanese Dwarf Gardens.—The following extract is from "Notes and Sketches from the Wild Coasts of Nipon," by Captain H. C. St. John, R.N.: "I have alluded more than once to their diminutive gardens, but I hope a more detailed description here will not be considered tedious. These gardens generally represent some particular scene, and the locality of some favourite temple is frequently chosen. The avenue leading to the shrine, the water, the trees are exactly carried out, all alive and growing, the trees only a few inches in height, the running river of similar proportions; men's figures, proportioned to the trees, are modelled and placed about, just as seen when visiting the temples, or whatever particular scenery the garden represents. Storks and deer, or wild duck, all most absurdly life-like, are also placed about, and the whole garden is kept in this state perpetually. The art of nipping back the proper shoots of these tiny dwarfed trees is thoroughly understood. My Japanese servant made one of these gardens for my cabin; it was about 3 ft. long and 2 ft. wide. It possessed a fine specimen of Pinus Massoniana, several species of Palm, an Oak of grand proportions, a lake on which wild duck were always to be found, and fish of two or three species. Tortoises lived in the long Grass by the margin of the lake. Beautiful Ferns sprang from the Lichen-covered rocks, and occasionally I found a lovely female quietly seated under the shade of the overhanging trees, evidently enjoying the tranquil scene across the lake. Next day a gentleman would arrive, and after much toil would reach the summit of the highest mountain, where he rested, looking far across the country below. I had this garden for a long time on board, and it was a never-failing source of amusement and entertainment."—H. R.

Waterproofing Boots.—In answer to several questions on this subject, I give the following recipe: Take—drying oil, 1 pint; yellow wax, 2 oz.; spirits of turpentine, 2 oz.; and Burgundy pitch, 1 oz., melted over a slow fire. With this composition rub the boots over at a distance from the fire as often as they become dry till they are fully saturated. The leather then is impervious to wet, and lasts much longer than it otherwise would. Thus runs the recipe. Now for my own experience with regard to it. Taking an old, but strong and sound pair of boots, I used this preparation, only substituting common black pitch for the Burgundy (I have since tried the latter, but did not find it so good as the common sort). When the boots were dry, about three weeks or a month after they had received the dressing, I put them to a severe test by walking two miles out and home in a deep snow, and remaining on the snow for two hours assisting in a pyrotechnical exhibition. On taking off my boots I found them quite dry inside and not the least trace of wet on my stockings. After wearing them two or three times they began to take the blacking, which they would not do at first; and with the moderate amount of wear they had to undergo I found that one dressing of the composition was quite sufficient for one season. Of the durability of boots so treated I have no doubt, but they should not be worn till the leather has become quite dry, which need not be more than three weeks if they are kept in a warm dry place. But the best way is to dress them in the summer and not put them on till winter has fairly set in.—B. S. [We have lately received from the inventor of Gishurst Compound some tins of a preparation for boots which our readers may like to hear of. It is called Gishurstine. It is very clean, softens the leather, and keeps the water out—at least so far as our experience of it goes.—It is sold by Price's Candle Company, Battersea.—Ed.]

Protecting Plants from Frost.—It may in this severe weather be of some service to your readers to know that common newspaper, or brown paper, placed round the glass of greenhouses will effectually protect the plants from frost, as I have proved this winter to my gardener's great wonder and satisfaction. —Erin.

Making Plants Hardy.—Nothing contributes more to rendering plants hardy for enduring the sharp cold of winter than a dry bottom. In the first place, a dry soil induces an early ripening of the wood, and we have known this early ripening to make more difference than 20° in temperature. A wet soil causes a late and watery growth, which is easily winter-killed. In the second place, trees and plants standing in a soil not soaked with water will bear greater cold than the same trees water-soaked at the roots. It is well always to bear these facts in mind, and to act accordingly.

VEGETABLES.

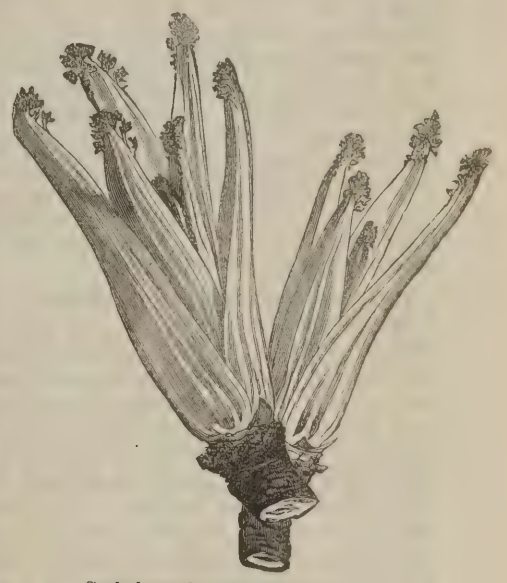
Brussels Sprouts. — These are both hardy and prolific, the severest winter usually leaving them unscathed; and by sowing two or three times at short intervals, a successional supply of this delicious, compact vegetable may be obtained in plenty from October to March, while the old stems will afterwards produce several dishes of tender young greens. Sow a pinch of seed early in March, and again about the end of April. In cold, late situations, this and several other winter Greens may be advantageously sown thinly in September, left in the seed-bed during the winter, pricked off early in spring, and put out finally early in May. This treatment insures an early start, and consequently a long time for growth; and where an autumn supply is desired, it will be found a very good plan to adopt, but though it involves more labour, and the crop occupies the land for a longer time, yet a fuller development of the plants and a better and earlier crop are thereby secured. In many cases an early crop is not required, therefore the March sowing would be early enough, with the April sowing to follow on after Christmas and lengthen out the supply. Although they will make a good return under any reasonable conditions, yet deep, somewhat strong land suits them best. They may be planted immediately after the early Potatoes, if the land be in fair condition, without much preparation, and again a later crop in July wherever land may be vacant. Those plants that are put out early will require rather more space than the later crop—2 ft. apart each way will not be too much for the former if the land be in good heart; whilst for the late crop, 20 in. between the rows and 18 in. between the plants in the rows will suffice. There is a considerable variation in this vegetable, therefore it is important to have seeds only from a reliable source, whether imported or home-grown, I think, matters but little if the stock have been selected with care.—H.

Early Peas.—In most places Peas sown in autumn, unless covered with glass, will this season be a failure, but he who takes time by the forelock will be prepared for this, and there is more than one way of filling up such a vacancy. The simplest and, perhaps, on the whole, the best, is to sow again about the middle of this month as many Peas in 5-in. pots as will make good the loss. The pots may at first stand under a stage, or in any position where a little warmth can be afforded them; but as soon as the green tops push through the soil, they should be taken to a cold pit or frame, and have plenty of ventilation till the weather is suitable for planting them out, which will generally be about the middle of March. There are warm south borders in most gardens available for the earliest crops, and if they can be planted near the foot of a south wall they will sustain no check. The planting should be done when the soil is in a good mellow condition. The sticks should be placed to the rows at the same time, but a few Yew or evergreen branches of some kind should be placed on the windward side to afford shelter. There are other ways of forwarding early Peas under cover all more or less useful, such as cutting pieces of sod about 1 ft. long and 6 in. wide, scooping out the soil along the centre, sowing the Peas, and covering with light, rich soil; then they should be placed in a frame where there is a little warmth, and after undergoing the hardening process, planted out turf and all without disturbing the Peas in the drills in the border; a ridge of warm, mellow soil should be drawn to each side of the rows. Early Peas should be planted rather thick, as it is not often they yield more than one or two good gatherings, and the second crop comes in so quickly after them, that they are not required for continuous bearing, even if they were adapted for it, which they are not. If the roots are broken or disturbed the crop will not be so good, as Peas do not transplant well if the roots are broken. I have sometimes transplanted them when quite small from boxes where they had been sown thickly, taking them up in little patches, and transferring them at once to the drills, but I have always found the less the roots were disturbed the better the crop turned out. For the earliest crop there is nothing much better among white Peas than Ringleader. William the First is a most desirable kind to sow early in the open ground.—R. H.

Pumpkin Seeds Germinating Inside the Fruit.—In September I cut a Pumpkin 11¾ lb. weight, and it was hung up until January 13. When on opening it I found it had germinated above a dozen seeds, and have them now with seed leaves above the fruit.—J. Dodsworth, *St. Mary's Terrace.*

Raising Early Peas.—Ever since the plan of sowing early Peas under glass for transplanting to the open ground has been practised the use of strips of turf for the purpose has been known and advocated. The plan has some obvious advantages over pans, pots, or even boxes of a certain character, but its weak feature consists in the fact that either the turf must be placed on some hard substance, into which the young roots cannot enter, and thus promote weakness and degeneracy, or, if placed on some soft material, such as soil or manure, the young roots soon penetrate it freely, and the disturbance caused to these when transplanted is productive of much mischief. There is yet another danger when strips of turf are used; the turf may contain wireworm or other dangerous insects, and roots of the young plants might be eaten. If the plants be turnod out of pots, pans, or ordinary boxes, then the young roots must be seriously disturbed, and we all know that when plants are so moved from under glass to the open ground, say in the month of March, that it takes some time to get them established and ready to take advantage of the shift to make the required progress. One plan that I have known from experience to answer famously is having a lot of narrow boxes, of, say 2 ft. in length, 4 in. deep, 2½ in. wide on the top, and 3 in. wide at the bottom, inside measure; these are made with moveable bottoms, kept in their place by means of hooks and eyes, two on either side; these are filled with soil, the Peas sown, and then placed together in a frame, where they can remain until the plants are 4 in. in height and ready for transplanting. When this is done deep drills are drawn, the boxes are inverted, the bottoms taken off, and the frame containing the Pea plants placed lengthways in the drill; owing to the shape of the box it will lift freely from the plants without disturbing the roots, and these are found to have formed a mass ready at once to take hold of the new soil. Twenty of these boxes may be made in a short time, and to secure the correct form it is but necessary to cut the ends of the right size—2½ in. by 3 in.—and all the rest will follow. These boxes might be used with advantage in the autumn for striking cuttings of bedding plants.—A. D.

Hints on Raising Seakale.—The propagation of Seakale is accomplished by seed, division of old stools, or by cuttings from the fleshy roots. The seeds should be sown in March or very early in April, but generally speaking most places will afford old stools or old plantations from which new plantings may be made, and sets may be bought ready for planting. They should be planted in lines at from 2 ft. to 3 ft. apart—say 2½ ft., to be precise—and if they are to be forced in the old and useless way, there should be a space of 2 ft. or so between the plants, so that each may be readily found under the usual bed of dung, or under a Seakale pot. The main object should be to make the plants grow as freely as possible, as the bigger the leaf the larger the bud, and the larger the bud the bigger and better the Kale. Pinch off all flowers in the bud, unless you want to save seed, and that is not likely to happen often. If the soil is liable to drought, a mulching or thin layer of some light, half-rotten manure, Cocoa fibre, leaf mould, old Hops, or any fluffy material that can be most easily obtained, will do much good, particularly the season after planting, before the roots have reached down deep and got out of the way of surface drought. Most people cut off the crown or bud of the plant before planting, because if planted whole it would be likely to run to seed, and the secondary buds that spring out around it naturally have not that tendency at first. But it is of little matter, and, indeed, none at all, provided you have a look or two over the sprouting plantation, and see that the buds inclined to run to flower and seed are nipped out early. Do not be satisfied with removing the flower-stems, but nip them out before there is anything of a stem to speak of. Although it matters little what mode of propagation is employed, it may be remarked that not a few of the old growers prefer sowing their seed in thin lines or patches, where it is to remain, and thinning out the plants to proper distances apart when they come up. When the Seakale, in its wild state first begins to swell up through the sand in spring, it is delicious to eat; and it was thus that the west country people used to enjoy it, about a century ago, before it was introduced to our gardens. How few of any vegetables since introduced to gardens possess the grateful virtues of this native root? But I was going to remark that, though it is prime when it comes in naturally, yet few people are satisfied to wait till it reaches



Seakale ready for the Kitchen.

that stage, and it may be had in good condition from before Christmas till March, with but slight expense or trouble.—S.

TREES AND SHRUBS.

Camellias Out-of-doors.—One of the best aspects for Camellias is a south or south-west one, sheltered by a bank or wall. They flourish in a compost consisting of two parts fibrous peat and one part good turfy loam, with an addition of sharp sand. Planting from pots may take place at any period from March to October, but about July is the best time, as the wood is then well ripened. Duke of Devonshire, Halfida, Chandleri, Florida, imbricata, elegans, Alberti, Double White, Donkelaari, Countess of Orkney, Mathotiana, and Lady Hume's Blush are the best for outdoor culture, but in severe weather the flowers will be often damaged unless temporarily sheltered.—W., *Exeter.*

Planting Holly Hedges.—Hollies succeed best when moved in April or May and dull weather, if possible, should be chosen for the operation. August and September are also favourable months for transplanting Hollies. The ground intended for the line of hedge should be trenched from 18 in. to 24 in. deep, and from 3 ft. to 4 ft. wide, turning out bad subsoil and stones and replacing them with rich soil or fibry turf well chopped up and intermixed with the original soil in the line of fence. The plants should be from 12 in. to 18 in. high, bushy and well rooted, and planted just clear of one another. Of course smaller plants will succeed equally well and cost less money, but a longer time must elapse before the hedge will be a sufficient fence against cattle, &c. If the weather and soil be dry when planting wash the soil in amongst the fibres with a liberal soaking of water; finish off the planting by adding a thick layer of litter, Bracken, or any rough herbage

over the roots; this will prove a sure safeguard should a dry summer follow after planting. All the attention that is necessary for two or three years is to keep down weed growth about the necks of the plants. When the latter have become fairly established, and have made vigorous growth, their sides may be slightly trimmed, encouraging a broad base and narrow, wedge-like top. Holly hedges should not be topped until they have attained the desired height necessary to form the desired fence.

Chimonanthus grandiflorus.— This most fragrant and free blooming of all winter-flowering hardy shrubs is now about at its best in a rather sheltered corner of my walled-in kitchen garden, and is most useful for cutting from, now that there is such a scarcity of any kind of flowers, and its blooms last many days in perfection in water after they have been taken from the tree. This large-flowered variety of the bettter known and much more generally grown ordinary Chimonanthus (or, as some still call it, Calycanthus præcox) is in every respect superior to it and much to be preferred to it as, in addition to the individual blooms being very much larger in size, they are also much brighter, being deep straw coloured, whereas those of the ordinary variety are only dull white, of a somewhat dingy hue. It is also a very much more abundant bloomer, an almost equally large bush at the opposite corner of my garden of the common variety having only an odd bloom here and there scattered over it, whereas the large-flowered kind is literally covered with bloom from top to bottom. The perfume much resembles that of a Jonquil.

Propagating Ivy from Layers.— Ivies naturally layer themselves as they trail along the ground, and, in that case, all that is needed is to cut the runner across with a spade, lift it carefully with its rootlets attached, and transfer it to its new situation. In layering Ivies artificially, select good shoots, stretch them out on the ground, place small pots under their joints at intervals of about 15 in. or 18 in. apart, cut the joints half-way through and in a longitudinal direction for about ½ in.; then peg these joints into the pots, which should be filled with a sandy compost, placing some sand about the incision, and cover the joints over with the ordinary soil to the depth of 1 in. or 2 in. By doing this early in the spring, and pinching out the point of the shoot after it begins to grow, layers thus treated will be found to be pretty well rooted by autumn, when they may be separated, and wintered in frames if badly rooted, but, if well rooted, a sheltered place outside will suit them. When very badly rooted. they may be left uncut till spring. Ivy may also be layered in the ordinary way without the aid of pots.

Tropæolum speciosum.—I find that in order to ensure success with this fine scarlet-flowered climber, it should be well established in pots before it is planted out, and during growth water should be freely supplied. It succeeds best in well-drained rich soil.—D.

Sweet Peas.—Flowers of these are always valuable in a cut state in summer, and, where they are required at that season, now is a good time to sow the seed. A moist situation and a deep soil should be chosen for them; they will then bloom in profusion for months in succession.—S.

Salvia splendens.—Now that the period of flowering is about over with this plant, I should like to impress upon those who have a good stock of it, and usually consign them to the rubbish heap, the desirability of keeping them till all danger of frost is over, and then planting them out either in groups or mixed beds for an autumn display. Treated in this way, the effect produced by them is quite striking. We had a mixed bed of these and Chrysanthemum frutescens last year which was much admired, the bold masses of the scarlet Salvia being toned down by its more delicate neighbour the Chrysanthemum. Fuchsias of different colours may be used for bordering the bed.—A. H. R.

Chrysanthemums.—I read in "Notes and Sketches from the Wild Coasts of Nipon," by Capt. H. C. St. John, R.N., "In my own garden in Gloucestershire I have plenty of Chrysanthemums. In Japan this flower is grown in a very different way. On a single stalk about 4 ft. long a single flower is allowed to remain, which in due time has become as large as a good sized Cabbage, or 20 in. to 24 in. in circumference. The long petals curl over each other, forming a charming great white ball. I have often been perfectly astonished at the size and beauty of the flowers."—H. R.

Calliopsis or Coreopsis.—These are valuable hardy annuals, growing in any deep rich soil, and flowering in the greatest profusion. For supplying cut blooms they are among

Calliopsis bicolor nana.

the best of annuals, and they should always be grown for this purpose. They make under good culture specimens from 1 ft. to 3 ft. in height, which bloom throughout the summer. Seed may be sown in August or September for spring and summer blooming, and in March for autumn display. The following are the best kinds, with their colours and height: aristosa, yellow, foliage very ornamental, 2 ft.; bicolor grandiflora, yellow, crimson centre, 2 ft.; b. nigra speciosa, rich velvety crimson, 2 ft.; b. nana, yellow, crimson centre, 1 ft.; b. nigra nana, velvety-crimson, 1 ft.; cardaminæfolia atro-sanguinea, deep velvety crimson, growth beautiful, 1½ ft.; coronata, rich yellow, spotted crimson, a very effective border plant, 1½ ft.; Drummondi, yellow, crimson centre, a charming plant for beds, 1½ ft.; filifolia Burridgei, crimson, edged yellow, very graceful and beautiful, 2 ft.; Engelmanni, bright yellow, in habit and foliage the very perfection of grace, 1 ft.; auriculata, rich

Calliopsis cardaminæfolia.

yellow, 3 ft.; grandiflora, fine yellow, 3 ft.; lanceolata, golden-yellow, 3 ft. The last three are hardy perennials, and valuable where cut flowers are in demand, as they afford for a long time a constant supply. They are easily raised from seed, like the annual kinds.

Select Lobelias.—I do not admire white Lobelias, they are so dingy; indeed, all the so-called white kinds are anything but white; these, therefore, will have no place in my list, nor will the purple or lilac varieties, as I consider them worthless, or, at the best, ineffective either in masses or lines. Only the true blue varieties are really effective in the flower garden, and the best of these are the following: Blue Beauty, a rich dark blue with a white eye, is always covered with flowers throughout the entire season, and rarely exceeds 6 in. in height; its growth is very dense, and, unlike the pumila section, it is not liable to damp off on account of its density (I have given up growing the pumila varieties because of that fault). Blue King, another good kind, is an exact counterpart of Blue Beauty, with the exception of the colour of its flowers, which are light blue. Blue Stone is the darkest flower I have yet seen, and, but for its disposition to produce nothing but flowers, would be in every way a most desirable variety; as it is if planted very thickly to make up for its sparse growth it is most satisfactory. Ebor is a near relative of Blue Stone, but of the two the better grower, and both are fine dwarf kinds. I am, however, by no means sure that both must not succumb to St. Martin's Blue. There are numerous other good varieties, but the above constitute the cream of the many kinds that I have grown.—W.

Wooly Yarrow (Achillea tomentosa.)—This is a most useful plant, growing, as it does, close and compact. It has bright yellow flowers, which are never an annoyance even when faded, although we regularly remove such as are past their best in order to ensure a constant succession of flowers for six or seven months. One must step occasionally on the borders, and we use this and similar plants set at intervals apart as stepping-stones—a gentle kicki n dry weather, or rain in wet, will put all to rights again. A. aurea is beautiful, but not so easily increased as tomentosa; it has long bright foliage, and clear yellow flowers; it grows about 1½ ftr high, and is beyond the stepping-stone line. A. Millefolia rosea is also good, but it is rather straggling in habit for choice borders. We grow many Achilleas; no weateer injures them, and they are useful even when faded. The dwarfest which we have is A. tomentosa; the variegated form of the native A. Millefolia, which has a beautiful leaf, is the tallest; A. ægyptiaca, is 2½ ft. A. Ptarmica fl.-pl., a desirable variety, has double flowers, and is pure white. A Clavennæ, which has hoary foliage, and which is a dwarf grower, we use as an edging alternately with another wild plant named Geum athamanticum. By cutting off the flower-shoots and a portion of its leaves we secure the beautiful feathery foliage of this Umbellifer during the whole season. Naturally after flowering it dies down, and the edging is gone. It is impossible to exhaust the countless hardy plants that grow on one's memory. and possibly our borders—none of which can be cast out; all have much interest and beauty, and the variety is endless—that, perhaps, is the greatest charm of such plants.—F. J. H,

The Autumn Flame-flower (Tritoma grandis).—This takes a prominent rank amongst Tritomas because it keeps so late in flower. I have a plant of it not very large which has flowered ever since September, and even until recently has been in full beauty, being furnished with some ten spikes. The colour is also bright and fine, and the spikes are a little larger than those of T. Uvaria.—M. L.

Eccremocarpus scaber on Wire Arches.—Some seed of this was sown indoors without artificial heat late in the autumn of 1879. In the spring of last year a plant was transferred to the garden, the position selected being against a wall in a sunny situation, though in comparatively poor light soil. It soon started into vigorous growth and having obtained hold on an arch of galvanised wire netting repaid its new-found friend for the support thus afforded by clothing its nakedness in a garb of a most attractive character. The orange-red flowers, which it produced in great abundance, were, it is true rather dull of tint to be striking, but the habit of the plant, its bronzy foliage, and rapid growth made it a general favourite. Of course it looked none the worse for its proximity to a mass of profusely-flowering Sweet Peas, while Clematis Jackmani and Canary Creeper disputed with the intruder the ownership of the spacious arch. I should perhaps add that the garden referred to is situate on the sea-coast of County Down, Ireland.—G. G. P.

Sweet Peas for Garden Decoration.—Amateurs are generally advised to sow these in the open ground, and it is often suggested that they should be sown in November or January, being as hardy as the ordinary culinary Pea. Now, while I do not question the truth of the latter statement, I must advise those who, like myself, are not particularly fond of hazardous experiments in gardening, to act differently. I find that by sowing indoors in pots or boxes about the middle of February, and, when the young plants are 1 in. high, gradually hardening them off, Sweet Peas acquire a sturdiness and toughness which, when they are planted out in good, well-manured soil in April, conduce to rapid growth and immunity from the attacks of birds and slugs, which otherwise feast upon the tender shoots the moment they appear above ground. During the last ten years we have been accustomed to grow Sweet Peas thus with most satisfactory results, while others who sowed too early or in the open ground have met with repeated disappointment. Sweet Peas look remarkably well when grown as hedges or pillars; in either case the ground should be well trenched and plenty of good stable manure worked in, and after the plants have been rather thickly dibbled in, they should have suitably arranged supports of galvanised wire netting placed round them, and then, with a little attention during dry weather, and regular removal of the incipient pods, they will produce wonderful quantities of beautiful and deliciously fragrant flowers all through the summer and autumn.—G. G. P.

Camellias Out-of-doors.—It may be interesting to many to know that, from information gained in this paper, I planted last May in the open ground a few of my worst Camellias as an experiment. One has been in bloom for the past fortnight, and at the present moment looks quite gay. They withstood the last frost without any protection, but I have now placed a little loose manure round their stems.—G. H. A., *Springfield, Chelmsford.*

Primula amœna.—In order to have vigorous plants of this Primula in full bloom in spring it is necessary to divide the old roots every year into small pieces, and pot them in equal parts of turfy loam and leaf-mould, adding plenty of road sand or in lieu of leaf-mould well decayed cow manure may be used with advantage. Good drainage, plenty of water, air, and light are also essential. Thus managed, healthy, vigorous plants, well furnished with Fern-like leaves and a profusion of showy rose-coloured blossoms, may be obtained. A number of plants placed 5 in. or 6 in. apart in deep pans make also effective objects for placing in vases or on pedestals. As a basket plant, too, this Primula may be used with advantage.—C. S.

Common Garden Marigold (Calendula officinalis).—This is one of the best of biennials for autumn and winter flowering. Nothing short of severe frost will prevent it

Common garden Marigold (Calendula officinalis).

yielding abundance of rich orange blossoms. For late blooming seed should be sown in July. Its blossoms are always useful for cutting for vases, &c., and last a long time in water.—V.

Collinsia bicolor.—This is one of the prettiest and showiest of hardy annuals. It may be sown in the open ground in window boxes or pots, in either of which ways it is sure to give satisfaction. The soil should be rich and well drained, and the seed may be sown early in March. When up thin the plants to 5 in. or 6 in. apart each way, and when well established a few small sticks may be needed to support them. A little manure water during dry weather is an advantage, as is also a mulching with rotten manure or Cocoa-nut fibre. For pot culture sow at once in light soil, and place

Collinsia bicolor.

the pots or pans in a frame or window. When well up and fit to handle, prick the plants out into other pots of rich soil, say five plants in a 6-in. pot. Keep them close for a day or two, and when again established, expose them to sun and air. They will flower well in June or July, and may be used for room decoration with good effect. Seeds sown in the open ground in April will give a display of bloom in September. When well grown this Collinsia assumes a pyramidal branching habit, and grows to 12 in. or 18 in. high.

House and Window Gardening.

Table Plants.—In Gardening, Jan. 1, you recommend as a good table plant Casuarina sumatrina. Two kinds grow very freely at Madras and Bangalore, and seeds could be easily procured to put your advice to the test. As they germinate quickly and grow very fast, there would be no difficulty in raising such plants by the autumn of this new-born year. Will you let me recommend also the trial of two other very fast-growing trees for a similar purpose: Poinceana Regia and Grevillia robusta, either of which would make a greater show, particularly the former, with its elegant Fern-like fronds? There is only one objection to it, and that is, that the seeds, with their very hard integument take a long time to make any show, unless they are gently filed and forced, after the method practised by the Bangalore native gardeners. In this way they start in about ten days; the young plants are very showy. I have a few seeds left, but they are four years old and would probably fail if tried, but I expect some in a few days of selected kinds from Bangalore, and will send you a packet for trial; but I have seen them advertised in one or other of the recently-issued seed lists. For the hanging baskets (figured at page 520 of the same number), I would suggest, in addition to the Convolvolus mauritanicus, the trial of several kinds of the dwarf Thunbergia; T. aurantaica, T. alba, T. alata, and T. coccinea, are very effective when well grouped. Ipomœa Quamoclet, red and white, have a charming effect together, and I. ficifolia, or dissecta, I am not sure which, has elegant foliage and a lilac flower. Maurandia Barclayana, blue and white, look well together, and can be trained to any shape with great ease. Eucalyptus globulus, with its glaucous foliage, may be added to the list of table plants; and Acacia robusta, with its very singular foliage, may be tried.—J. P.

Preparing for Spring.—The time is now rapidly approaching when seeds may be sown and offsets and cuttings rooted to take the place of those plants that are lost. Amongst seeds that may be sown now in some of the empty pots are those of Sweet Peas, which will be available for either the inside or the outside of the window. Sow about twenty Peas in a 5-in. pot. They may stand anywhere till the green tops appear above the soil; then they must occupy a position in a light, sunny window, as without plenty of light they will grow too weakly to flower well. If the pots could be suspended in a light window, as I have sometimes seen them, and the Peas encouraged to flow over the top of the pot as they progress, aiding them a little whenever the tendrils seem inclined to disarrange the proper spreading of the shoots, they will have a very pretty effect by-and-bye. They will require plenty of water and a small quantity of some artificial stimulant. Outside the windows they may be planted in boxes, and either be suffered to hang down or be trained up. Anyone having a flower border may fill their empty pots with various plants from that source. Many hardy plants are well worth potting up in autumn and making a special feature of, without any reference to losses or deaths of other plants from severe weather. Hardy Primroses of the commom type in various colours are now in bloom in a cold house; so are Polyanthuses, and Alpine Auriculas are, in some instances, showing their trusses, and such things at this season are more capable of giving pleasure than half dead and withered specimens of Pelargoniums, &c. They should be potted not later than September, and be set on the north side of a wall or fence, and well supplied with water. In November plunge the pots in coal ashes, and if severe frost sets in before they are required for the windows scatter a little dry litter over them, or a few evergreen branches laid over them will suffice. Bulbs of all kinds may be potted up for windows, and if that operation be carefully done they will experience no check. I have lifted clumps when in bloom and potted them without injury, and they may be returned to the border when their flowering season is over.

Cuphea platycentra.—This is a pretty little plant for windows in winter. It strikes freely from cuttings in spring, and if grown in 5-in. pots, and kept pinched back during the summer, it makes bushy little specimens, fur-

Cuphea platycentra.

nished with red, tube-shaped flowers, with white-edged petals. It is sometimes used in the flower garden during summer, but it is not showy enough for that purpose.

FRUIT.

Orchard Notes.—Orchards are commonly cropped year after year until the diminished yield shows that something must be done. The proper way is to give a moderate manuring annually; stable manure put on in the fall and ploughed in, or in small orchards forked in, may be alternated with ashes or lime in other years. Clover to be pastured by sheep or pigs, and after ploughed under, is one of the best fertilisers. Trees of forced growth are more tender than others, and so suffer more from sudden changes of climate. For this reason too high cultivation is as bad as not enough. Wood ashes are the best fertilisers for trees, vines, and bushes. Prune Apple trees so as to give them a low, well-balanced top.

Early Strawberries in Pots.—Having now grown Vicomtesse Héricart de Thury

Strawberry for the earliest forcing sort for several years, I find it by far the best which I have ever tried. The Black Prince will, perhaps, come in a week earlier, but it is subject to mildew, and does not set so freely as the Hericart de Thury, nor is it so finely flavoured. For other two successional early varieties, President and Sir Joseph Paxton do well with me; and last year the Grosse Sucrée, which I can recommend as a good early forcing sort. The early forcing Strawberries are grown here in pits, where the shelves are near the glass. The shelves are of iron and are about 1 in. deep, so that when the sun begins to have some strength in March and April they are filled with weak liquid manure at times. This keeps the roots of the Strawberry in the bottom of the pots well supplied with moisture, and causes the fruit to swell to a better size than when the plants are grown in the usual way.—W. T. W.

Saucers for Strawberries in Pots.—The great evil arising from the use of these is having them too large, whereby they hold so much water that the plants standing in them are drowned, and the roots, therefore, instead of being healthy and active are just the reverse, as must, of necessity, be the case when the soil is always in a wet, sodden condition. Whenever I use them, I always have such as are made for pots a size smaller than those in which we grow Strawberries (6-in.) and then the pots do not quite reach the bottom of the saucer; most of the water in that way which they contain is drawn up by capillary attraction, and is all taken out and made use of during the twenty-four hours. It will be found a good plan where saucers are larger than they should be to nearly fill them with sandy shingle or broken-up horse manure mixed with leaf soil, or anything of that kind that will not get muddy through being so much saturated with water. By managing in this way, plants standing in large saucers are almost if not quite as well circumstanced as those in others of smaller size, as so long as the earthenware of the pot remains in contact with the moist body of matter beneath, it will absorb water from it and give off part of it to the roots.—S. W.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

Feb. 7.—Potting off variegated Pelargoniums struck in boxes; also Verbenas, and putting them into heat, and a batch of Gloxinias; shifting Hollyhocks and Centaureas into larger pots, and placing them in orchard-house; putting in cuttings of Iresine Lindeni, Impatiens Jerdoniæ, Salvia patens, Fuchsias, Coleus, and Gesneras, the latter consisting of leaves; making hills for Cucumbers, in order that they may get warm and ready for planting; dividing Dactylis glomerata var. and Poa trivialis elegans; staking early Peas; strawing up ice-house doors and making safe against sudden change in the weather; fumigating greenhouse for fly and thrips; examining Stephanotis for scale; applying a mixture of lime and soot to Pear trees and Red Currants, as birds are attacking their buds; taking up Artichokes and Parsnips; manuring Rose border ready for digging; stopping the shoots of bedding Calceolarias.

Feb. 8.—Putting in cuttings of Salvia and Mesembryanthemum cordifolium; getting all bulbs out that have been plunged in ashes, and putting them where they can be just protected from frost; dusting Apricots with soot and lime to prevent sparrows from eating their buds; raking up worm-casts on Grass.

Feb. 9.—Preparing a bed under south wall for Radishes; potting off Chrysanthemum Sensation, Veronica variegata, and Gazania; putting in Verbena cuttings; planting Seakale for next season's forcing; regulating creepers in conservatory; top-dressing Lapagerias with good peat and sand.

Feb. 10.—Digging among Currant trees; sowing Melons; putting Zonal Pelargoniums into their flowering pots; potting Lilacs; shifting some potted-off Petunias into 4½-in. pots for early flowering; putting in cuttings of scented Verbena; planting Artichokes.

Feb. 11.—Potting Gladioli in 3-in. pots, and placing them under greenhouse stage to start; planting spare cases with Cauliflower; putting in more Strawberries to force; repotting young tree Mignonette; tying up climbers on verandah; pricking manure into Asparagus beds.

Feb. 12.—Potting off young Fuchsias, Lobelias, Chrysanthemums, and Tuberoses, putting the latter in heat; pricking out earliest Celery in a one-light frame; also Tomatoes, seven to a pot; putting in Mrs. Pollock Pelargonium cuttings; also Pink cuttings in manure-bed, and some Plumbago; shutting up Maréchal Niel Rose-house to induce the plants to bloom; syringing Cherry trees with soapsuds to kill any fly which may be lurking in crevices; finishing the pruning of Gooseberry trees.

Flower Garden.

The protracted frost will have delayed planting generally, but advantage should be taken of the earliest opportunity to recommence and finish it. All kinds of deciduous trees and shrubs should be planted as soon as possible; Roses should also be planted during the present month, as the season for active growth is near, and the later the planting is deferred the greater will be the loss, and growth weakly. Roses delight in a rich, deep loam, well broken, and with an admixture of manure. After planted thus, a top-dressing of manure annually will suffice to keep them in a vigorous condition for several years. They are somewhat impatient of being disturbed at the roots, therefore digging or forking the beds should be done carefully. Dwarf kinds are in every respect much better adapted for beds than standards—in fact, the standard form is little likely to induce persons to grow Roses at all, on account of its unnatural appearance. If a proper Rose garden is impracticable, a well-arranged bed or border entirely devoted to their culture will prove far more enjoyable than double the number of plants indiscriminately dotted about the grounds like inverted mops.

Anemones and Ranuncluses may now be planted in the beds that were manured and deeply dug some time ago. Herbaceous Phloxes are extremely useful and free-flowering plants, and make very effective groups. Irises are again becoming deservedly popular, for besides the gay colours of their blossoms which enliven the open borders, they are very effective and serviceable in a cut state. Other useful plants are the Evening Primroses, the large yellow flowers of which are very showy. Beds wholly of one kind, or edged with a dwarfer-growing kind, are amongst the simplest of the many ways of disposing of the host of really good herbaceous plants that one seldom sees except in mixed borders, where the strong-growing too frequently overrun the weaker kinds, but which, arranging them according to height, would both show to advantage. Any operation in connexion with lawns should be completed forthwith. If sufficient good turf is procurable, that is decidedly the quickest and best way, but on a large scale sowing with lawn Grass seeds is the best substitute. If the land has been trenched and allowed to subside it should be now well raked, and the seed sown evenly over the fine surface, raking it in and rolling frequently afterwards, in order to get a smooth, even surface. If showery weather follow, the seeds will quickly germinate, and as soon as the Grass is sufficiently high it should be cut with a scythe.

In places where there are many trees and shrubs isolated on the lawns, it is impossible to dispense with the scythe, as the mowing machine cannot safely be worked round them without great risk. Mowing machines needing repair should be seen to at once, so as to be ready when required. On mild days the lawn should be swept so as to remove wormcasts, and also a heavy roller passed over, as the smoother and firmer the surface the better for mowing. In some places Daisies, Dandelions, Docks, &c., are very troublesome on lawns, and the best remedy is to draw them out by the root, for, although various remedies are said to be effectual for their removal, none are so efficacious as drawing them out of the soil entire, and then sowing some good lawn Grass seed, covering it with fine mould and a dressing of soot and wood ashes.

Carnations and Picotees.—While the frost continues, not much can be done to these plants. As soon as there is a change of weather it will be necessary to examine the plants carefully and remove any decayed leaves. Though some of the leaves may be decayed at the base of the plants it does not follow that they are in bad health, but if the leaves continue to decay at this season after those that decayed in the autumn were removed, it must be the result of mismanagement. Let the frames be made perfectly close fitting, and fumigate with Tobacco two or three times during the present month, so as to prevent the attacks of green fly rather than a means of destruction.

Auriculas.—Those who have seeds of Auricula should sow them at once, so that good flowering plants may be obtained for next season, whereas, if the sowing is deferred, not so many flowering plants will be obtained. If the seeds are sown now, it is best to use a small shallow pan, well drained, filled nearly to the top with soil, and the surface inch of soil should be fine and sandy. The seeds should be just covered over with fine soil, and a square of glass placed over the surface, so as to leave a space between the soil and the glass. The pans should be plunged in a gentle bottom-heat, but there ought to be but little atmospheric heat.

Dahlias.—In case of there being a large demand for any particular sorts, the roots of these should be potted and placed in a gentle heat, and at the same time should be kept moderately moist. Shoots will soon be produced, and these should be removed when about 3 in. in length. If a successive set of cuttings be expected quickly the first must not be cut too close to the old crowns. The principal collection of roots need not be placed in heat for a month or even more. It will, however, be necessary to examine them, and see that there is no signs of decay, or anything to cause it.

Hardy Cypripediums.—These comprise such an interesting class of plants, and so suitable for cultivating in frames, that they must not be passed over in the present remarks. C. spectabile, C. pubescens, and C. Calceolus grow and increase most freely in a house from which frost is excluded. Repot the plants just before they commence to grow.

Polyanthus.—Seedlings of these are very desirable, and the plants make a fine display in the open borders. Still, the named varieties, when well managed, seldom die off from any cause excepting the attacks of red spider or green fly, which so debilitate the plants that they succumb to a severe winter.

Glasshouses.

Ferns.—Those who have collected spores (seeds) should now sow them on peat. Break the peat into pieces about the size of Peas, and prepare a few well-drained 3-in. pots by filling them to within ½ in. of the rim with peat. Set them on an even surfaoe and give them a thorough watering. The spores should be carefully sown while the surface of the soil is damp. The pots should then be set in a shady part of a warm house or room. The pots should be placed in a pan containing 1 in. of water, which must be replenished as it evaporates. The surface of the soil in pots must not be watered, as the capillary attraction from the water in the pan will be sufficient. Each pan, which should contain about a dozen pots, should then be covered with a bell glass, and kept close until the surface of the soil becomes green, when a little ventilation will be required. Such kinds as the following are best adapted for raising in rooms: Pteris cretica albo-lineata, P. serrulata, P. tremula, P. umbrosa, Polystichum mucronatum, and the various kinds of Lomaria and Lastrea that thrive in a greenhouse temperature.

Camellias that have bloomed should now be placed in a growing atmosphere, and any repotting should now be done. The soil best adapted for the Camellia is a mixture of fibrous peat and loam in equal portions, with a liberal quantity of sand and broken crocks. All the plants should now be examined, and any of the commoner kinds that do not require repotting should be top-dressed, but disturbing the surface-roots of choice hard-wooded plants should be avoided. Calceolarias, Francoas, and all herbaceous plants may receive liberal shifts. The autumn-blooming Heaths should now be breaking freely, and if they need larger pots they should now be repotted. Overcrowding should be avoided now that the plants are commencing to grow, and during mild weather ventilation should be applied freely night and day.

A batch of Pinks from cold frames should now be got forward. The best kinds for forcing are Lady Blanche, Derby Day, Lord Lyons, Anne Boleyn, and Ascot. Myosotis (both white and blue), also the different kinds of early Primulas and Anemone fulgens, should be forwarded gently in heat. Azaleas that are past flowering should be placed in a moist atmosphere, and kept well syringed so as to induce them to break freely. Double Primulas that are past their best should be divided for propagation. A safer method, however, is to place a little very sandy soil about the base of the plants; in this

they will soon form young roots, and the old stools can then be divided without any loss from damping off. These Primulas are so useful and so beautiful, that they amply repay any labour bestowed on them.

Fruit.

Orchard House.—By this time the general stock of trees intended for fruiting in the orchard house will be under glass, and properly supplied with water in sufficient quantity to prevent the blossom buds from falling. This important point having been secured, the flowering should be retarded as much as possible by throwing open all the ventilators when it is not actually freezing, as we may have a repetition of the late spring frosts that have so often injured the crops in unheated houses.

Melons.—In order to secure a few extra early Melons, some of the strongest plants may be selected from the first sowing for special treatment in the hottest and in other respects best adapted compartment at command. Improved Victory of Bath, Eastnor Castle, Read's Scarlet, and Turner's Gem still occupy the front rank when flavour becomes the test of value; moreover, they are good growers, free setters, and mature their fruit early. For this kind of work the grower must have full command of top and bottom heat from pipes, plenty of light, and a good supply of sound Oak leaves or tan. The beds and pots having been prepared as directed in my last, and planted in the compost recommended, train up the trellis, and allow the leaders to grow without stopping them until they begin to throw out side shoots, which will, under generous treatment, show fruit at the first joint. When four female blossoms on each plant can be secured for fertilisation, the leaders may be pinched out, and as soon as a pair of nicely-balanced Melons can be seen swelling away evenly together, everything in the way of lateral growth must be kept constantly pinched and thinned out to prevent overcrowding, care being taken that all the stem leaves are preserved, as a means of securing the rapid flow of the sap and immunity from canker at the joints. When fairly in growth ply the syringe freely, give food in proportion to their strength, and allow the heat to range from 70° to 90° by day from sun and fire-heat combined. Plants intended for pits and frames should be stopped at the third or fourth leaf, and allowed to break again before they are removed from the nursing frame to the hills. Guard against making the hills or ridges large at first, as the soil is liable to scald. Make frequent sowings for succession in pits and houses, always bearing in mind that plants for training up to and over a trellis must be potted on and encouraged to make a vigorous vine; while plants for ordinary beds require stopping as soon as they get well into rough leaf, and that, in either case, sturdy young plants are more valuable than older ones that have become cramped and pot-bound.

The protracted frosts, though they delay the planting and dressing of fruit trees and the borders, will in other respects be advantageous, inasmuch as it will retard the flowering season, and the later this is the greater will be the probability of a fertile setting; but even yet it is well to be prepared for the worst weather, therefore let coverings be in readiness for protecting wall trees. Peaches, Apricots, and Pears all need protection to ensure their safety; next to glass, movable blinds are the best protectors, but where these cannot be had, netting, Yew branches, twiggy Birch sprays, bracken, or finely woven straw screens are good substitutes.

Plums and Cherries are hardier than the kinds above named, and bear a few degrees of frost without injury; but even to these slight protection should be given. As soon as favourable weather sets in, and the state of the soil admits, all planting should be completed, as also should every other operation that necessitates the disturbance of the roots, so that any newly formed roots may become established in the fresh soil before there is any risk of their being checked by drought. With the exception of Figs all other fruit trees may now be pruned, and those against walls, before they are retrained, should be well syringed with soap-suds, the walls also, as a preventive against green and black fly. This application will not kill the scale, and so for this pest the trees require to be painted over with a strong solution of soft soap and sulphur, or with Gishurst at the rate of 6 oz. to each gallon of water.

As soon as all bush fruits are pruned, it is a good plan to splash them all over with a moisture of lime and soot, which is distasteful to small birds, which do much injury at this season; and at the same time it cleanses the trees of Moss and Lichen. Point over all the ground amongst bush fruits, and then apply surface mulching of manure, but it should never be dug in. Grafting Apple and Pear trees may be commenced as soon as milder weather sets in. Stocks on which to operate cannot be too vigorous, neither can the scions be also, provided the wood is well matured.

Vegetables.

The remains of spent crops, such as Cabbages or Brussels Sprouts, should be cleared off, and preparations made for other crops. Make new plantations of Horse-radish, Jerusalem Artichokes, Rhubarb, Garlic, and Shallots. Tansy, Tarragon, and some other herbs should have their crowns divided, and fresh plantations made, if necessary, with the divisions. Some Chives for early use may likewise be protected; also some Parsnips and Jerusalem Artichokes; in fact, the two latter should be lifted altogether, the first to be stored and the room given to other crops, the last to be re-planted. Turn manure heaps at the same time, saving the roughest litter for protecting vegetables and for covering frames.

Cucumbers.—If any of the winter plants are to be kept in bearing through the summer, the surface roots should be encouraged to make their way over the tops of the pots into good friable, turfy loam—somewhat heavier than that used through the winter—placed on tiles to prevent the roots from striking directly into the bed of leaves. Succession compartments now in full bearing will require generous food, constant attention to stopping, and the entire removal of useless spray, from which clean, handsome fruit cannot be expected. If not already done, turn out the first set of spring seedlings before they become pot-bound, and train up sticks to the trellis without stopping. Pinch the points out of others intended for pits and frames, keep them near the glass, and give another shift into larger pots, in preference to planting out, before the manure beds are quite ready for them. Keep sowing a few seeds to make up losses, as well as for succession, as it is always better to have plants to throw away than to feel the want of them. Collect Oak, Beech, or Spanish Chestnut leaves for future use. Just now they are in fine condition for harvesting, and if protected from wet they will keep sound until next autumn.

TOWN GARDENING.

Window Gardening Outside.

This is, as a rule, suitable for the summer season only, as few plants, especially if in pots, will live exposed to the open air in winter in a town. About the only plants we know of that will stand such an ordeal is a good strong Carnation, a pot of Thrift, which is a splendid town plant, and does well in a pot too; Adam's Needles, Yuccas, and Ivy of various kinds. The former we have seen exposed in a small pot on an open windowsill through all seasons, and yet growing, and every autumn producing numbers of beautiful flowers.

Boxes *v.* Pots.—It is a very usual plan to keep pot plants indoors during the winter, and to put them outside on the sill in summer. This is a very good plan in theory, but not in practice. One great objection is, that plants in pots on a dry position like a window sill, exposed to the air all round, so quickly get very dry in summer, that unless you are constantly watering they are in a chronic state of flagginess, and often become withered and stunted. This constant watering, besides being a great labour, is very injurious to the plants. But beyond this where the window faces anything like south, the pots are exposed to the full blaze of the summer sun, and soon get so hot that the tender rootlets coiled round the inside get scorched and destroyed, and so the plant suffers and sometimes dies. And again the pots are very apt to get blown down and broken by wind; so that it is far better in any case, and for south or southerly windows almost absolutely necessary to have the pots protected in some way, and the best means of doing this is to have a suitable box, and sink the pots in this, surrounding them with Moss, tan, Hops, Cocoa-nut fibre refuse, or any open material, both to keep them steady, and retain moisture, or the box may be filled with suitable soil, and the plants set out in this, just as if it were a garden bed, and perhaps on the whole this is the simplest and best plan in most cases, though the other plan has its advantages.

Form of Box.—The box should be as large as possible, *i.e.*, it should be as long as the sill itself, and as wide as this also, or wider for it will be a great advantage, especially if the sill is narrow, to allow it to project a few inches beyond; it can easily be supported by iron or wooden brackets, or held up in some way, so that if you can extend it to 8 in. or 9 in. in width, or even more, it will be far more serviceable than if it were only 5 in. or 6 in. The depth need not be great, certainly not so much so as to look unwieldly or awkward, from 5 in. to 7 in., or 8 in. inside being plenty. A very good size is the length of the sill, say 2 ft. 6 in. or 3 ft. by 6½ in. wide and 5½ in. deep, inside measurement, though make it wider if you can, but this size can be made without any cutting except sawing the lengths off from a piece of flooring board, which can be had for a very low price at any timber yard. The usual price is 1d. per foot, so that supposing your windowsill is 3 ft. long, you want three lengths, one for each side, and one for the bottom, with 1 ft. extra to make the two ends, and the whole will only cost 10d. Nail the two sides on to the edge of the bottom and the ends inside; eight or ten holes should be made with a ¾-in. auger in the bottom, and three or four cross strips, about ½ in. thick, be nailed on the bottom, so as to allow the water to run freely away. The box would be the better of a a coat of paint outside, but leave the inside plain, or it may be thinly coated with a mixture of clay, cow manure, and water; green or a good chocolate we consider the best colour. If you want to ornament it, get some straight stakes, such as stout Beansticks, cut into lengths with the bark on, split them in halves, and either point the tops and nail them on outside, round side out all along the front, or cut them to fit, and fasten them on in diamonds, squares, or any convenient shape; or a few pieces of virgin cork may be tastefully disposed on the front. In any case, varnish over the whole when completed.

Most plants grow more freely, and become more dwarf and compact in habit when planted out in soil in the boxes, but when the pots are plunged you can change one that has gone out of bloom or become unhealthy for a fresh one, or turn the plants round, or re-arrange them afresh. So you must consider your resources, and do which you like best; but if well done and all the plants healthy, the planting out gives the better general effect, especially if you have a neat border of Lobelia or Golden Feather, and then you can put the plants in so much closer, and have more than if they were in pots.

Soil for Window Boxes.—In preparing a box for filling with soil, put a good large flat crock or piece of broken tile over each hole, and then cover the bottom with about 1½ in. of crocks, bricks broken small, or ballast; on this a layer of old spent Hops, or littery half-decayed manure, and fill up with soil. The best for this purpose is that recommended for potting, viz., two parts of good fibrous loam or and decayed turf and one part each of leaf mould well-rotted manure with a little crushed charcoal and sand. But any good garden soil will do if not too fine or rubbishy, mixed with a good proportion of old decayed manure: the leaf soil is not absolutely necessary, but have fresh country soil if you can get it. Make the soil pretty firm, especially at the bottom, and set the plants cut, the smallest in front (outside) and the taller ones behind. Give a good watering to settle the soil and the box is complete. Where the pots are to be plunged, no drainage, except a crock over each hole, is needed, but just set the pots in their places and pack the Cocoa-nut fibre, or what you have, firmly between and among them. Of course in this case the pots must be watered separately as required, but it is well to keep the plunging material moist also.

Arranging the Plants.—A few arrangements of common easily-grown plants are given as under: 1, a scarlet or white Geranium and a stiff-growing Fuchsia alternately for the back row, having a Geranium at each end, and a border of Lobelia or Golden Feather, or these arranged alternately along the front; 2, a tall old white Fuchsia, such as Mrs. Bennett, in the centre, with a good scarlet Geranium on each side of it, and smaller Geraniums, Fuchsias, or yellow Calceolarias again on either side of these with an edge as for the last, or you may break the monotony by having a drooping Fuchsia, such as Mrs. Marshall, to hang over the front in the centre, or one at each end; 3, a Balsam (white) and a scarlet Geranium, or white and scarlet Geraniums alternately along the back (but the white Geraniums do not do so well or flower so freely as the scarlet and white variegated Geraniums, like Flower of Spring, do not grow so well, so that we think the Balsams best), and a row of Petunias or a white Petunia and a Lobelia alternately along the front; 4, same as the last, but have a white Stock alternately with the scarlet Geraniums, or a white and purple Stock alternately with the same bordering or any of those mentioned (Creeping Jenny makes a splendid edging for a box, especially in a shady window, it hangs over the front so beautifully); 5, Stocks in alternate or any variety of colours for the back, and a row of Mignonette sown previously along the front (this will grow and droop over, and you will have a bouquet with these two); 6, a row of Tom Thumb Nasturtium or Tropæolum, scarlet, sown in its place in April, and thinned out as required for the back, and a row of white Petunias or Verbenas along the front. These may be transposed or added to *ad libitum*. It is a great improvement to sow a few seeds of major Convolvulus at each end of the box, and let them run up strings properly arranged, or a couple of long withies or canes bent over and stuck in at each end so as to form an arch. This looks very pretty, and another plan is to get a couple of young roots of Virginian Creeper, just little rooted pieces with two or three shoots just starting, and put them in at the ends and train them over. We have, unfortunately, never tried Thunbergias for this particular purpose, at least not in town, though they do splendidly in the country, but we recommend giving them a trial; they are wondrously pretty, especially the dark-eyed ones, and will stand anything almost, but they have to be raised in heat and planted out early in June.

Godetia Whitneyi (New Spotted).—This is a strain of beautiful blothed and striped varieties, remarkable for the great size and brilliancy of the flowers. The individual blooms are of great size, frequently measuring 4 in. to 4½ in. across, and vary in colour from the most delicate satiny white, stripped with pale rose, to the most beautiful carmine and crimson, all the petals being distinctly marked with bars of a deeper colour. The plants, which grow about 1 ft. high, are of the same robust, compact habit of growth as the old G. Whitneyi, and should consequently not be planted closer than 9 in. or 1 ft. apart. This fine annual, which is perfectly hardy, is now being offered by Messrs. Daniels Brothers, of Norwich, to whose illustrated guide we are also indebted for a very good engraving of Camellia-flowered Balsams given on p. 587.

Protecting Window Plants.—Few people seem to realise the protection there is in common brown paper, or the ordinary paper on which newspapers are printed. In a fairly well constructed dwelling house, if the plants be taken from the windows in the evening, placed in a corner near the fireplace free from draught, with a newspaper thrown over them, they would generally be safe; but only the most patient and thoughtful are capable of following out any such plan to the end. I have known cases in which the greatest pains have been taken to protect the plants for a time, and then perhaps on some particularly sharp night they have been forgotten, the whole previous trouble thus counting for nothing. As soon as it can be clearly seen which plants are really dead and which are not, those that have perished should be thrown out, and the pots washed ready for their next occupants.

GLASSHOUSES AND FRAMES.

GROWING BALSAMS.

As regards colour of flower, Balsams comprise the most delicate tints of scarlet, salmon, maroon, rose, white, purple, &c., and the blooms rival in beauty, substance, and form some of the smaller species of Camellia. Of late years the blossoms of Balsams have deteriorated sadly, so that it becomes necessary in procuring seeds to see that they come from a trustworthy source.

Sowing.—The cultural details, though simple enough, must have attention at the proper time, or the foundation of a specimen plant cannot be laid. To have good specimens early in July the seeds should be sown in March; if for late work, the sowing may be deferred till the middle of April; or if the plants be intended for front rows or small stages, and only intended to occupy 8-in. pots, a safe calculation may be eight weeks from the time of sowing till the plants are in bloom. The culture of large specimens differs little from that of smaller plants, if the latter be well managed, except that a defective foundation will be more obvious in the former than in the

New Spotted Godetia.

latter case. In sowing the seeds it is necessary, in the first place, to make the usual preparation by having the requisite number of clean 3-in. pots crocked, and the soil ready to proceed with the operation of sowing. The different colours will be best kept by themselves and legibly named. The pots should be filled with mould about half-way up, and two seeds should be dropped into the centre of each (if both seeds germinate, one of the plants will, of course, be pulled out) with the name of the colour attached. If the pots be kept together, the seeds can be covered thinly through a fine sieve, and taken to a warm frame and plunged. I prefer beds where the heat is on the decline, as, for instance, one that has been used for propagating purposes till the heat had abated to a gentle warmth, so that something like natural time may be given for germination, and growth may not be unduly hastened.

Potting.—When the young seedlings appear above the rim of the pot they should be earthed up, leaving the usual space for a supply of water. It may be necessary at the same time to raise the plants nearer the glass by a fresh addition of half-spent material to make up for the subsidence that took place during fermentation. At this stage especially it is of the utmost importance to have the young plants as near the glass as is consistent with safety from breakage when giving air or from scorching in case of changeable weather. Water through a moderate-sized rose, and ventilate on all favourable occasions, in order to secure short, stubby growth; better admit a little air, even if it be necessary to do so through a piece of fine canvas, if the weather should be unpropitious, than to give none. In a week or ten days the young plants will be ready for a shift into 5-in. pots, and will have made two shoots at the base of the perpendicular one on either side; those that do not behave in this way should be either potted for packing plants, *i.e.*, filling in between other pots, or thrown away, as they never made handsome specimens. A fine day should be chosen for removing them from the frame to the potting bench, and the material in which they are to be potted should be a rich compost of good soil, cow manure, and rough leaf-mould, well incorporated and warmed to the same temperature as that in which the plants have been growing. The pots should also be warmed before they are crocked. In potting let the two bottom shoots hitherto mentioned be trained horizontally level with the rim of the pot.

Airing, Watering, &c.—When the potting has been completed they should be returned to the frame and plunged, making allowance this time both as regards height and width for the rapid progress which they are sure to make under the conditions adverted to. The bottom-heat at this stage will be about enough to accelerate fresh root action and impart tone and vigour to the plant. The frame should never be quite closed under any circumstances, and the more air that can be safely given at all times the better. Another pair of shoots will soon be produced at the base a little higher up, and these must be pegged down as previously indicated. These four shoots form the foundation of the future specimen, and the upright stem will soon clothe itself with a number of shoots, which must be taken in hand in a similar manner.

At the next shift the ultimate size of the plant must be determined. A 10-in. or 12-in. pot will be quite large enough for all practical purposes, and as the requisite conditions this time are identical with the last, it will be unnecessary to go over the same ground again. Up to the time at which the specimen is fully grown I would recommend a gentle warmth at the root. The plants should also be given plenty of room for a free circulation of air to play among them. When they have become re-established after their final shift they will require almost daily attention to training. A frame-work can be made of sticks painted green, with a piece of tar cord forming the extremity or outer line of the circle, and an inner circle might also be formed in the same way to facilitate the process of training. The leading shoot will, of course, be tied to an upright stake, and as the plant furnishes itself, every shoot should be drawn in a downward direction by means of a piece of matting suspended from the outer extremity of the frame-work to the tip of the shoot. Each shoot pulled down in this way will break out at every point into a number of other shoots, and so on till the specimen attains the desired proportions.

The flowers should be picked off the earlier-formed growths as they make their appearance till the plant has become furnished and well proportioned from top to bottom, after which flowers may be encouraged, and, if necessary, the plants may be taken to any house in which there is plenty of light till such time as they are ready for the embellishment of the show house or conservatory. These plants require careful attention in watering, and will almost live on liquid manure throughout the whole growing season in case a rich compost is not at command. W. H.

Hardy Primroses under Glass.—For several winters I have had coloured varieties of garden Primroses in bloom more or less the whole winter through. Fearing a sharp winter, I have always lifted a number of plants and re-planted them under glass in a temperature of from 40° to 45°, and they have well repaid the trouble by a fine display of broom, while those that were out-of-doors still looked as if spring was in the remote future.—J. G. L.

ANSWERS TO QUERIES.

4090.—**Erecting a Cucumber House.**—Sink the house about 1 ft. in the ground, with about 2 ft. of brickwork above the ground level, on the top of which the wall plates supporting the roof should rest. The roof should be a fixture with a double ridge piece, and a movable cap worked by a lever for ventilation. The roof must not be too steep for Cucumbers, or the atmosphere in the house will become so dry in hot weather the red spider will be troublesome. It will be better to sink the pathway a little more, and be contented with a little less head room inside than to run any risk. I lay some stress upon this point because I know a case where the roof was built to catch every ray of sun, thinking the Cucumbers would like it, and the moment the plants grew up into the roof the red spider was upon them, and nothing availed to alter it till the roof was taken off and the rafters shortened, and then all went well. I should rather have the house stand north and south end on. When building the walls put in a couple of air bricks near the ground line on each side; they can be easily closed in cold weather. I need say nothing about the flue, as any bricklayer knows how to build one that will draw well, and that is the chief requisite. Supposing the house to be 7 ft. wide, the space inside might be divided by three, forming a bed or pit on the east side for Cucumbers, a stage on the west for plants, and a path down the centre. The flue should be taken along under the stage, first to give top-heat, and return under the bed for bottom heat, covering it in with slates or boards.—E. H.

4086.—**Grafting Fruit Trees.**—The stocks may be planted as soon as the weather breaks, but they must not be grafted this spring; let them have time to get established. If they were grafted the young trees would not do much the first year. They might be budded in July, and budding produces good trees. The Paradise stock was so named from its supposed origin in America, where it is thought the Garden of Eden was situated. It is chiefly valuable on inferior soils on account of its surface-rooting habit. The true Paradise stocks are generally raised from layers or cuttings. The free stock is obtained from sowing Apple pips, and are consequently seedlings. The English Paradise stocks are often selected from the weaklings possessing a surface-rooting habit in a bed of seedlings. Where a large quantity of Apple pips are sown some will develop a surface-rooting habit, and these often make excellent dwarfing stocks.—E. H.

4102.—**Transplanting Pear Trees, &c.**—If the land is naturally dry, there will be no draining materials required in the holes, which should be deep enough to permit of the trees being planted about the same depth as before. In making the holes plenty of space should be allowed to lay the roots out straight and something over, so as to surround their extremities with good friable soil for them to fibre into. Fill in the holes with the turfy loam, and mulch with the old hot-bed manure. The question of cutting back the trees can only be decided on the spot. If lifted carefully with plenty of roots don't cut back, but stake or otherwise secure the trees from wind-waving, or all your labour will be in vain.—E. H.

4091.—**Growing Mushrooms.**—There is no reason why your idea if carefully carried out should not succeed; but I should not recommend fowls' manure; it is of too burning a nature. Use stable manure, and either ferment it for ten days or a fortnight before making up the beds, so as to drive off some of its rankness, or else mix a fourth of loamy soil with it, to absorb the gases and reduce the over-heating liability to a safe medium condition. Obtain good spawn and keep in a dry, warm place until it is used.—E. H.

4100.—**Manuring and Planting Fruit Trees.**—Peruvian guano is the best artificial manure for general purposes. Bones in any fresh form or in the form of phosphates are also good. All of the manures mentioned may be applied by scattering them at the rate of 3 cwt. in the case of the former per acre, and 4 cwt. or 5 cwt. in the case of the latter, and lightly forking them in, blending and mixing them well with the soil. They may also be profitably used in rather less quantities as top-dressings during spring and early summer to the growing crops. Either or all of the manures I have named are good for fruit trees. Soot is also excellent for a top-dressing. House slops and liquid manure of all kinds will be beneficial. If very strong they should be diluted. The Chestnut and Oak trees should be removed before the fruit trees are planted. Plant Pears and Plums on the fence.—E. H.

4089.—**Laying Down a Lawn.**—You may safely fill up to the proper level with good mould, only in the places where the good new soil lies deepest some means should be adopted to firm it, or it will settle unequally; treading or rolling may suffice. Sow plenty of good seeds about the end of March or beginning of April. The old Grass if it breaks through will be no disadvantage. The mowing machine and roller during the summer as soon as the new Grasses can bear its weight will put matters right.—E. H.

4087.—**How to Grow Cucumbers.**—Before answering Mr. T. Box's question I should like to ask him one or two, viz.: When does he want to cut Cucumbers? and what heating power has he at his command? Cucumbers in winter and early spring should have a night temperature of 65° with a rise of 10° or more in the daytime. There should also be a little bottom-heat either from hot water or fermenting materials, but when the plants have fairly settled down to their work, I think a bottom-heat of 75° is quite sufficient. I believe in some cases the plants are injured by too much bottom-heat being employed. Provision must be made for moisture in the atmosphere either by having pans on the pipes or by syringing the walls and paths. Turfy loam with a third of old hot-bed manure, leaf-mould, or dried horse droppings will form a good compost to plant in. Unless your correspondent can command the temperatures I have given, he had better not begin too early; April will be time enough to start his plants. Cucumbers are easily grown in a greenhouse in summer with only sun-heat. French Beans may be grown successfully with Cucumbers in any stage, as they require the same temperature and same atmospherical conditions, but they should occupy a light position.—E. H.

Camellia flowered Balsam.

4083.—**Culture of Eranthemum pulchellum.**—The young free shoots of this plant should be taken off in February, dibbled singly into small pots in a compost of sandy peat, and placed under a hand-glass or in a frame in a warm house. As soon as they appear to be well furnished with roots, inure them to the general atmosphere of the structure, and in the course of a week or so shift them into 2½-in. pots, using a sweet compost of peat and leaf-mould in equal proportions, adding enough coarse silver sand to it to ensure its remaining free and open. This plant likes during the summer a moisture-ladened warm atmosphere, but at the same time it enjoys the free admission of light, and should therefore be placed in the lightest position in the house, and not, as too often the case, be placed in the partial shade of other plants. The amount of bloom and its quality entirely depends upon the employment of a suitable compost, congenial atmospheric conditions, and the vigour of wood and foliage engendered by a free admission of light throughout the growing season. The final shift should be given in June into 4½-in. pots, this time adding a little loam to the compost. Towards the latter end of the summer admit air more freely and be careful with the syringe, as the object is at that time rather to arrest growth and solidify the tissues. Old plants from which cuttings have been taken should be allowed to start, and then have the greater portion of the old soil shaken away from them, and be replaced in the same sized pots to be shifted on when required.—J.

4110.—**Propagating Tuberous Begonias.**—Cuttings may be taken of the young wood as soon as the plants have come fairly into growth. It is not, however advisable to take them off too early, or the mother plant suffers a check. When the tubers start into growth, shake them out and pot them in a nice free compost of half leaf-mould and loam, ensuring porosity by throwing into it a good dash of silver sand. Let the pots be only just large enough to contain the fibres; if these latter touch the sides of the pots no matter, as the object is to make the old roots throw out fresh fibres, and this they will do most readily when they are so situated that the soil around them cannot by any means become even slightly overcharged with moisture. In a short time they will need shifting into larger pots, and it is just when they have grasped this fresh body of soil and have commenced to derive benefit from it that the cuttings may be taken, as they will then be free, and the plant will be sufficiently vigorous to withstand the slight check entailed upon it by their removal. Cut the young shoots to some three joints, and insert them in sandy peat, keeping the soil moist and the atmosphere clear until they have formed roots.—J.C.

4073.—**Coal-ashes for Paths.**—Coal-ashes are excellent for paths, as they allow of killing the weeds with the hoe, which cannot well be done where gravel is employed.

4084.—**Azalea mollis and sinensis.**—Both these Azaleas can be forced year after year if the plants are guarded against injury when brought out of the glass structure. When removed from the conservatory they should be placed in a cool, airy house or in a cold frame, so that they may be protected against inclement weather, and by getting plenty of air on all favourable occasions, will be gradually hardened off and be fitted for their residence in the open air. By the latter end of May they should be removed to some sheltered situation in the open air, taking care not to allow them to become dry at the root, and so placing them that they are well screened from cutting easterly or rough westerly winds. The success to be derived depends in a great measure upon the care exercised at this period, for if the foliage gets crippled or the root fibres perish, the plant does not recover in time to furnish itself that year with sufficiently robust and matured wood to form good flower-buds. About the beginning of June, having well prepared a piece of soil in an open, sunny situation, work away as much of the old soil as may be done without

injury to the roots. Plant them out a good distance apart, mulch with some good manure, and water well in hot weather. In this manner the same plants may be made to do duty for several years.—J. B.

4109.—**Begonias for Bedding.**—The advantages to be derived from starting the plants in heat are that they will come sooner into bloom, and, if grown along freely, will form much larger specimens by the time that it is desirable to plant them in the open air. A tuber started say the beginning of March will have the advantage of coming freely into growth by the time those standing in a cool house will be starting, and will make a fine effect early in the season. We would plunge the pots, just as they are, in a hotbed about the first week in March, and when the plants have fairly started into growth we would shake away all the old soil and pot them in fresh, free, light, sandy compost, plunging them again in bottom-heat. By the beginning of May they may be placed in a cool greenhouse, giving abundance of air in fine weather, or they may be stood in a cold frame, as the object is, during that month, not so much to promote rank growth as to bring them into a sturdy, hardy condition, thereby fitting them for a residence in the open air. There is, however, no absolute necessity for starting the tubers in bottom-heat; if left to themselves they will commence to grow when the natural temperature allows of their so doing. In any case it is better to shake away all the old soil and re-pot, but use pots only just large enough to contain the roots, and in the case of the early-started ones shift when the soil becomes full of fibres.—G. C. B.

4081.—**Spiræas Decaying.**—We can only surmise that too much water has been given, with the consequent effect of rotting the roots. The answer to such queries as this would be much facilitated if correspondents would be a little more lavish of details. You do not say, for instance, whether the plants are in heat or at rest in a cool house or in a cold frame. If they have been standing in a low temperature, and were fresh potted up in autumn, they should have been very carefully watered, for although this plant when in full growth is greedy of moisture, and when coming into bloom is greatly helped by having the pot placed in a saucer to be filled up now and then with weak liquid manure, it is extremely impatient in its earlier stages of growth of stagnant moisture at the roots. All that you can do is to cut away with a sharp knife all decayed portions of root, pot the plants in light sandy compost, well draining the pots and giving just enough water to keep the soil moist. As the plants have suffered to a serious extent, we would not place them in heat, but would let them come along gradually with the season. During the summer plunge the pots up to the rims in a sunny part of the garden, and water copiously in hot weather with weak liquid manure.—C. B.

4111.—**Double Geraniums not Flowering.**—Double Geraniums as a rule are more gross of habit and are not so floriferous as the single varieties. They require a very light, airy situation in the open air during the summer, or to be placed near the glass in a well-ventilated, unshaded greenhouse. The latter is by far the best place for them, as they there acquire greater substance of wood and foliage, do not run so much to leaf, and develop and perfect their bloom in a much better manner than when growing in the open air. Unless a window is very light indeed, and free ventilation can be given, the double Geraniums are not likely to do well therein, and we should certainly always reccommend the single kinds in preference to them. All that can be done now is to keep the plants in as cool an atmosphere as possible, and when the brighter and milder weather comes give as much air as possible without exposing to chilling draughts. Then about the beginning of June place the plant in the open air in a sunny situation. If it is in a large pot we would not shift it, as these double Geraniums do not care about too much pot room; they never flower so freely as when the soil is crammed full of roots. In the summer a top-dressing of soot may be given, which will strengthen without stimulating too much.—C.

4105.—**Propagating Mulberry Trees.**—If "An Emigrant" requires Mulberry cuttings off Mulberry trees of the white varieties for rearing silkworms (or seeds, the latter direct from Italy), I can supply him with any number if he will write to me. It is a good distance to carry cuttings to North America, but if cut in mild weather with a little old wood at their bottoms, I doubt not I could pack them so as to go the journey, and they might strike roots in North America laid in the ground in a protected situation to keep them until the first week in April, and then plant them in 1 ft. of common sandy soil on a hotbed, shading from sun when hot until fairly rooted.—Leonard Harman, *Prospect Hill, Old Catton, Norwich.*

4097.—**Worms in Conservatory Border.**—We cannot do better than recommend the general recipe for killing worms, that is, strong lime water. It is invariably advised for the purpose named, and is easily made by putting one gallon of fresh slaked lime into six gallons of water, stirring well, and then allowing to remain for several hours till quite clear. Water the border freely with this mixture several times at intervals, and it is probable that most of the worms will be killed. As worms come out chiefly at night, no doubt if the solution were then applied it would be much more effective.

4099.—**Hyacinths in Glasses.**—It is well in the case of Hyacinths in glasses to remove them from the window during hard weather, as the water may get frozen. Perhaps yours may have suffered from that cause. The best water is that which is soft, and a piece of charcoal about the size of a marble is useful if put into the water, as it serves to purify the water and keep it healthy. Many growers of Hyacinths in glasses do not change their water from the time the bulb is put in till it has done blooming. Perhaps you may have changed the water, and in doing so given some fresh that was far too cold.—A. D.

4069.—**Warming and Ventilating.**—"G. S. C." is right in saying that oil gives a very unpleasant atmosphere and the cost is great. I tried two 1-in. wicks a year ago and found the heat therefrom quite insufficient, and the oil burned was a gallon per week, at 1s. per gallon, for night work only. My lean-to is now very efficiently heated by a flue under the front stage running once down the house; the furnace is about 2 ft. long by 2 ft. high and 1½ ft. broad; there is a sharp rise of 1 ft. from the furnace to flue, which is nearly level to the chimney; the chimney is inside, and passes through a galvanised iron pane in the roof; it rests on a brick base of about 4 ft., and is simply a piece of 6-in. piping with a damper inserted just outside the roof; the flue near the fire is of fire-brick (as the furnace must be); the rest may be common brick. I built the flue five bricks high and wide enough to allow tiles to rest thereon; these form the top of the flue. With this arrangement I can get up a heat of 65° with the thermometer at 16° outside, although the house being wood is anything but air-tight. I burn what is called at the gas-work breese; it is the cinder from coke partly burnt in the furnaces; it costs here 1s. per cartload, not including cartage. A load lasts me three months in mid-winter, but a little coal is necessary to get the fire started; when the heat is up, slake down the fire with the finer breese and ashes and nearly shut off the damper; your fire will then burn 12 hours easily, and need never be let out if you remove the clinkers from the furnace bars.—Pat.

4082.—**How to Propagate Mistletoe.**—Cut with a sharp knife a tongue in the shape of a letter V in the bark, lift it, and place the seed of Mistletoe under it. It is better to make this incision on the lower side of the branch, as the seed will be less exposed to destruction by snow and rain. Beware of the mistake of boring a hole in the wood to contain the seed. This is a common cause of failure in sowing the Mistletoe. On the Continent I have seen Mistletoe growing on Fir trees; it would be curious to try whether a Conifer could be inoculated here. In the spring a twig of Mistletoe can be grafted on a bough with occasional success.—Harold Russell.

—— Any time in the winter choose plump berries, and simply rub them on the bark of an Apple tree; the underside of a branch near the tree is best. The glutinous matter makes them adhere, and in a short time they will throw out little green claws, clinging to the bark. A small piece of wire net to protect them from the birds is the only thing necessary. I have grown it thus successfully.—S. M. M.

4103.—**Plants for Greenhouse.**—A lean-to greenhouse only 16 ft. long is far too high if it is 16 ft. that way also; 10 ft. would have been ample, made the house far more manageable, and better proportioned. You will do well to plant at the back of the house a strong climber like Clematis Jackmani, a Jasminum grandiflorum, or a Maréchal Niel Rose, or even all three should be planted to cover the wall at the back. That such climbers may thrive, they must have a border 15 in. wide, from whence the roots may run all under the floor of the house. Then your notion of having cork work fixed at either end of the house is very good, but some miniature rockwork of flints, pieces of granite, and burnt clinkers would be more enduring, and if in this were well intermixed some peat, earth, and loam, with leaf soil, many hardy Ferns and Mosses would do well. In such a lofty house there should be a stage for plants to lift them as near the light as possible, but if stood in the floor small plants will look very diminutive, and large plants will, perhaps, take up too much room. A small stove will, we fear, prove a poor protection in such weather as we have just experienced. A greenhouse if properly protected with fire-heat ought to be gay with Chinese Primroses, Cyclamens, Scarlet Geraniums, Camellias, a few Heaths, &c., and in it also Cinerarias, Calceolarias, Pelargoniums, Deutzias, Dielytras, and other useful plants to bloom later on. But all these things depend upon the heat given and suitable looking after.—A. D.

4095.—**Early Potatoes for Damp Soils**—We can advise you to plant nothing better or likely to be more profitable than the Early Ashleaf if you specially want to secure a quick crop. The Early Rose would no doubt give twice the bulk, but it is difficult to dispose of at a profitable price. You should get the Potatoes as soon as the hard weather is past and put them out thinly in light and air to sprout ready for planting in April. Soils that lie low and damp are far from being good for Potatoes; really they are the worst as a rule, yet yours may get plenty of sun in the summer and thus promote rapid growth. It is not a good plan to leave such soils lying flat all the winter; heavy rains beat down the surface and air is excluded. We cannot too strongly advise the immediate throwing the soil into sharp ridges 2 ft. in width; then early in April, if it be possible, lay long fresh stable manure along the furrows and fork it in; this will serve to keep the roots fairly dry and prevent the accumulation of moisture around them. After planting the sets in the furrows fork in the ridges lightly and leave till the haulm comes through.—A. D.

4106.—**Paraffin Oil as an Insecticide.**—Paraffin is certainly an efficacious insecticide, and we have been informed that it may be used for the tender growths of Roses at the rate of a glassful to a gallon of water. The greatest care must, however, be taken to keep the oil well mixed with the water when using it. We have never employed Castile soap, but should think that it would have about the same effect as soft soap, which is a cheap and powerful insecticide.—J. C.

4101.—**Amarantus caudatus.**—The plants in question had in all probability passed into a second season of growth, and the climate being favourable to them had attained a high degree of development. Love-lies-bleeding is an annual, but, like many of this tribe of plants, may by cultural care be converted into a biennial or even perennial. It is not probable that such good results would be attained in this country, but it would be worth while to keep a few young plants over in a warm house, and plant them out in rich soil in a sunny situation in June.—J. C.

4092.—**Christmas Roses from Seed.**—Gather the seed as soon as ripe and sow it immediately in the following manner: Well drain some pans or 6-in. pots and fill them to within ½ in. of the rim with well sanded leaf-mould and loam in equal proportions. Press the surface quite firm and water gently, but enough to moisten the whole body of soil. Allow the pots to stand an hour or two and then sow the seed, covering with ¼ in. of fine soil. Make the surface firm and smooth, water gently, and then plunge the pots up to the rims in a cold frame,

covering the soil with Moss, and placing a square of glass over each pot. Be very careful not to let the soil get dry, and do not take away the Moss until the young plants appear above ground.

1047.—**Lilacs in South Africa.**—All you have to do is to pot the plants in suitable soil when they are at rest, and keep them well watered. We see no reason why they should die after flowering if well attended to in the matter of watering; at the same time the Lilac requires good soil in which to make good flowering wood, and if you keep the plants in pots they must be well fed with liquid manure when growing.

4093.—**Covering Hot-water Pipes.**—In Yorkshire manufacturies it is customary to cover boilers and steam pipes passing from one building to another with a mixture of clay, horse manure, and shoddy or woollen waste, ground together to the proper consistency in a mortar mill. For a small quantity of piping, clay and fresh Cocoa-fibre will do equally well, and can be mixed together with a spade; as much fibre as possible must be used. When put on and sufficiently dry a coating of tar may be given, when it will last for years.—ALPHA.

4088.—**Culture of Humea elegans.**—Seeds of this plant should be sown in April or May, in a close frame. Keep the soil moist and the atmosphere cool, shading from sun until the young plants appear above ground, when they must be inured to a circulation of air. When large enough to handle, prick them out into pans of fine well sanded compost, consisting of two-thirds leaf-mould and one-third loam. Keep the soil moist, but avoid heavy waterings, and promote free growth by shutting up the frame early in the afternoon, sprinkling the plants overhead when so doing. I may here mention that the great point in the culture of this plant is to induce a free growth and maintain the same until it comes into flower. The Humea is naturally of free growth, delighting in a free rich soil and an atmosphere at all times considerably charged with moisture. The soil should never be allowed to become very dry, but heavy doses of water may not be given, or, as a result, we shall get brown and rusty instead of green healthy foliage, and although the graceful disposition of the flowers is a much admired feature in this plant, it certainly loses half its beauty when the leaves are in any way disfigured or have been checked in their development. Before the young plants can crowd each other, let them be potted off into small pots, still using a fine, free, and well sanded compost. Still keep them under glass, shading a little from hot sun, but admitting at all times plenty of air and drawing off the light altogether when the atmosphere is soft and balmy. As soon as the roots touch the sides of the pots, shift into 6-in. pots, this time using one-fourth of well-decayed manure in the soil. It is of great importance that the roots should not at any time become matted in the pot, as a root-bound plant comes into a stunted condition, from which it is at all times hard to move it again. The last shift will be into 8-in. pots, and by that time the plants will no more need the shelter of a glass roof, but may be placed in some sheltered situation in the open air, sprinkling them well twice a day in hot parching weather. By the middle of September they should be placed under cover, the best place for them being a light structure where the temperature does not fall much below 50° at night. A cool greenhouse will, however, do for them, but care must be taken to keep them free from chilling draughts and overcrowding. The following April shift them into 12-in. pots, give plenty of air during the spring months, and the beginning of June they may be placed in appropriate positions in the open air, or they may be employed to embellish the conservatory. During the summer they must be well fed with liquid manure or top-dressed.—J. C. B.

4109.—**Begonias for Bedding.**—I would say that unless the tubers are very small, such as would be obtained from cuttings of the previous year, they are better without artificial heat of any kind, which has always a tendency more or less to cause the tubers to decay. If carefully potted early in March and placed on the front shelf of a cool, lightsome house, they will soon start naturally into growth, and make stouter, hardier plants than those forced unnaturally into growth. Indeed, some bulbs, if they have gone to rest early, start again in February or even earlier in the following year.—W. E. G.

4110.—**Propagating Begonias.**—Tubers of Begonias may be safely cut into several pieces like a Potato, care being of course taken to have an eye or incipient shoot in each portion, and dusting the cut parts before planting with either lime or powdered charcoal, and letting them dry a little before putting into the earth. Cuttings should be taken off as early as possible in the season, if possible in May or June, as those put in later have hardly time to form tubers of any size for the following year's growth. I find the best method of striking them to be in pots of pure silver sand and water, packed as tight as possible.—W. E. G.

4129.—**Planting Potatoes.**—As regards the quantity of seed Potatoes to crop half an acre, it depends entirely on the sort you would like to grow. Last season I grew from 14 lb. of seed of Magnum Bonum 7 cwt. 29 lb. of Potatoes, with not a bad one in the whole lot. If you grow the same sort you will only require about 1½ cwt., as they require at least 3 ft. each way. You would not require much manure this season. I am informed that about one bushel of lime per rod or less is an excellent thing for the Potato.—C. B.

4131.—**Nicotiana longiflora.**—Sow the seed thinly, like other annuals, in a hot-bed. When growing freely transplant carefully into small pots, and eventually bring into the greenhouse to blossom. Keep moist, and do not expose to very hot sunshine. Soil light, with some peat. If kept over the winter, the plant flowers early next summer. It has but little fragrance, but it is well worth growing for its pure white flowers, and the treatment described has for many years proved successful.—M. W. MOLIM, *Stoke Newington.*

4098.—**Botanical Books for Children.**—I am glad to be able to recommend to "Miss V." a very simple book on gardening, viz., "Town and Window Gardening," by Catherine M. Buckton. It is published by Longmans, Green & Co.—CAROLUS F.

—— There is no better book than Youman's "First Book of Botany" (Kegan Paul), price 2s. 6d.; and for children from ten years old and upwards I should recommend Kitchenner's "Year of Botany," published by Rivington.—R. H.

4092.—**Christmas Roses from Seed.**—I sowed some seed in pots in the autumn, kept them in the house, and after two years they came up, and I think they were five years old before I planted them out. It is far better to divide a plant. Every little joint will grow and flower in quarter the time that seedlings will.—J. K.

4085.—**Onion Plant not Flowering.**—This plant does not flower well until the soil in the pots becomes thoroughly packed with roots. Do not shift your specimens, but expose them to all the sun and air possible during the summer months. The plant being of a succulent nature, it requires a large amount of heat, light, and air to mature the tissues.—C.

4149.—**Thinning Annuals.**—It is recommended to thin annuals. Why should they not be sown thinly? Does thick sowing induce the seeds to come up?—M. A. P. [Thin sowing is uncertain, inasmuch as some of the seeds may fail to germinate, or the young plants may be eaten by slugs. Whilst by sowing fairly thick a good crop of plants may generally be depended upon, and, moreover, the seed of most annuals is so cheap, and the process of thinning such little trouble, that there is no excuse for any one failing to be successful.

4150.—**Sooting Gooseberry Trees.**—*Clydeside.*—Sprinkling dry soot over Gooseberry trees is effectual to keeping birds from eating the buds.

4151.—**Frozen Plants.**—I have got a spare unheated greenhouse, and I was recommended to build a paper covering all over my plants, and did so. Yet the frost has sadly treated them. Still there is life in such as Petunias, Lobelias, &c. Shall I put them into a mild hotbed? or how could I save them?—J. M. [If you cut them back and place them in a hotbed they will doubtless throw plenty of cuttings, which will easily strike in a hot bed.]

4152.—**Index to Gardening.**—*Funnidos.*—You can have an index to Vol. I. of GARDENING post free for 1½d. from our office. The index to Vol. II. will be ready early in March.

4153.—**Window Plants for Children.**—*Orangman.*—The best three for exhibition would probably be Geranium, Fuchsia, and Musk, or you might give them seeds of Balsams, Mignonette, Lobelias, or some of the beautiful hardy annuals which are very cheap. Suppose you gave each child half a dozen small packets of seed, an equal number of pots and some soil.

4154.—**Binding Covers for "Gardening."**—Do you publish a cover for binding the yearly volume of GARDENING, and also the price?—ARTHUR. [Yes, price 1s. 6d. Order of your newsagent.

QUERIES

4155.—**Substitute for Pea Sticks.**—I have read the account of "Eboracensis's" substitute for pea sticks, but it is not quite plain to me, and as I think of trying it this summer, I write for further explanation. What are pegs and straining cords, and how are they fixed and used? What is tarred band? I used last summer some tarred string for my Peas which reached above the sticks, and it all slackened with the rain. "Eboracensis" says that this tarred band shrinks with the wet; is it so? as that would be a great benefit. Does "Eboracensis" mean that the standards are placed 7 ft. or 8 ft. apart? he says "the supports," and I am not quite certain whether he means by supports the same as the end standards of which an engraving is given. What size standards should I require for the very tallest growth of Peas?—F. C.

4156.—**Vegetables in Shaded Places.**—What vegetables can be successfully grown under Apple trees where little or no sun comes? The sun is over the trees nearly all the day, but not much direct. What varieties will succeed best? and any hints as to their cultivation would be welcome.—F. C.

4157.—**Potatoes for Clayey Soil.**—What Potatoes are the best for a wet, clayey, heavy, cold soil? I wish to grow a few for eating new as they are dug as early in the summer as possible, and one or two good keeping varieties for autumn and winter. What is the advantage of allowing the seed Potato to sprout well before planting? and should all the sprouts but three be broken off before planting? and what is the object of so doing?—F. C.

4158.—**Potatoes.**—Last year I grew a very heavy crop of Early Rose, as many as seventy Potatoes having formed on one root, of which twenty were very good size, some very large; but the blight having appeared in one or two roots it was thought advisable to dig the lot, and so not half of the yield that would otherwise have been was realised, because they were dug before they were properly matured. It was found in digging them that the blighted tubers were generally the largest and those deepest down, so that my gardener remarked, This has taught me a lesson; do not in future plant your seed so deep. These had been planted about 6 in. deep. Do you think it advisable not to plant so deep this time? Is there any truth in the gardener's remark? Again, I have noticed in many market gardens that the germs of Potatoes are very short and sparse? Is this owing to any mode of cultivation? I grew two sorts of Potato last year, which produced exceedingly tall haulms; one, Victoria, produced fine tubers, but the other sort, Champion, though the haulm was exceedingly high, 4 ft. or so, had hardly any produce. Is there any disadvantage in such heavy greens, or is there any mode of keeping them close down?—F. C.

4159.—**Turnip Beet.**—Is this variety of Beetroot as good for eating as the ordinary Beetroot? My ground is very stony, and so this shaped root would grow more favourably than the deep-rooting kinds. What is the best mode of culture and time to plant?—F. C.

4160.—**Lettuce.**—Nearly all my Lettuces last year ran to seed, although I kept them well watered? What is the cause and the remedy for this?—F. C.

4161.—**Onions.**—I sowed a bed of Onions very thickly to insure a good supply coming up, and hardly any came up. I think perhaps I may have planted them too deeply; would this be likely? and how should they be sown? I want a variety that will produce bulbs as near like the Spanish Onion as possible?—F. C.

4162.—**Hotbed for Raising Seeds.**—I want to know how to prepare a gentle hotbed for raising half-hardy annuals. I can procure manure from where a horse and pig are kept. How much will I require for a frame 6 ft. 6 in. square? Would the oldest manure or that which is fresh be the best? I want to have it ready by the end of February.—V. W.

4163.—**Celery for Stewing and Soups.**—I shall be glad if any reader would inform me of the name of the best Celery to grow for flavouring soups, and also of that best for stewing.—E. H.

4164.—**Aquatics in Tubs.**—I should be glad to know if in ordinary tubs kept in a warm greenhouse I should have any chance of successfully growing and blooming the red Water Lily (Nymphæa devoniana) and blue Water Lily (N. scutifolia). If full directions for growing these were given it would greatly oblige.—ERIN.

4165.—**Hardy Annuals.**—Will any reader kindly name twelve kinds of hardy annuals seeds of which could be sown in a cold frame, and give time of sowing?—W. E. B.

4166.—**Guano Water.**—What proportion of guano to water should be used for bedding plants and seeds?—W. E. B.

4167.—**Economical Greenhouse Heating.**—I am thinking of having a lean-to greenhouse built, 24 ft. long by 10 ft. wide, and propose for heating purposes to have a furnace with a flue running through the back of the house, a saddle boiler over the fire, to which is connected a 4-in. flow and return pipe running in front of the house. My reasons for this plan is as follows: By having a flue at the back of the house I get all the heat engendered by the fire, the boiler being the crown of the fire. I get hot water heat in front. By having the ordinary furnace instead of an iron stove &c., I can utilise all the fire refuse of the dwelling house, and not require much added fuel, such as coke, &c. The iron stove boilers will not burn this refuse. Can any one see any objections to my plan?—G. J. WILLIAMS.

4168.—**Water Plants.**—I have a bell-shaped aquarium, 21 in. in diameter, and 18 in. deep, in which I grow Vallisneria and keep minnows and gold fish. I sank a pot with a Palm in it last summer, which did well for a time, but now the leaves and stems have turned brown. Will it thrive in the spring? I tried an Arum Lily, but as the aquarium stands 2 yards from the window, it grew straggling and did not flower. I should be glad to know where I could procure the water plants mentioned in an article in GARDENING, Jan. 22? Also I have a tank in garden 4 yards square and 5 ft. deep, but round the sides is a stone ledge only 1 ft. under water. Would any of

the plants mentioned do well and flower if sunk in pots on the stone ledge?—S. M. M. [You can get the water plants mentioned in the article you allude to at any of the large London nurseries. Palms are not fit subjects for aquariums in winter; we would advise you to take your plant out; it may revive in spring. Hardy water plants would do well on the stone ledge of the tank you mentioned.]

4169.—**Wood-ashes and Manure for Lawns.**—I read in GARDENING that a mixture of wood-ashes and soot is a good manure for lawns. Will any one tell me where in London I can get wood-ashes? Is there any artificial manure without much smell, which would serve as an effective manure for lawns?—T. G. W.

4170.—**Watertight Boots.**—Can any of your readers give me a receipt of a preparation which will keep the water out of boots and shoes?—M. A. P.

4171.—**Plant Stands for Rooms.**—I shall be glad if any reader will suggest the best form of stand for plants in a sitting-room window. I may say I have always had a dislike to wire plant stands. My own idea is a narrow table corresponding in length to the width of the window, but with sides and ends to the top, forming a sort of box, the box to be lined with zinc. In this plant pots could be plunged, and surrounded with damp Cocoa fibre, with a covering of green Moss to give a more pleasing appearance. To my mind this would obviate many of the difficulties experienced in window gardening, as the pots would not then be exposed to such rapidly drying influences. As I have never seen or heard of a stand of this character, I should be glad to hear on the subject from any one who can give information, and also whether anything of the kind is made for sale.—ALPHA.

4172.—**Close *v.* Open Glazing Greenhouses.**—Has any one ever tried the difference between close laps in glazing greenhouse roofs and the plan of raising the upper pane so as not to lie close on the under one? This I was advised to do by a nurseryman; its chief benefit is allowing condensed moisture, &c., to escape, so that I have no drip, but I fear I lose much heat in winter, as I observe Tobacco smoke used in fumigating comes out at every pane. I suspect close laps would give me 10° more heat if necessary.—PAT.

4173.—**Polyanthus Narcissus Failing.**—I purchased some bulbs at an auction sale in November, 1878, of the above kind. I planted them immediately, and in April following they flowered well, carrying from five to seven flowers on a stem. When the foliage decayed I took them up and preserved them carefully in paper bags until November following, when I again planted them in the same border, which consists of a dark or Buttercup growing loam with a little leaf-mould added, expecting to see them flourish and flower as before, but to my disappointment they refused to grow. After waiting until the time they flowered the year before I took them up, and found the bulbs quite firm and good, having made roots downwards. I planted one of them in a small pot, and placed it in a window, which is now growing nicely, having filled the pot with roots, and the foliage is 3 in. high. The remainder I planted as before, but a little sooner, and upon examining one of them a short time since I found was near coming up. Will any one inform me if it is common for the bulbs to miss flowering? and also their proper treatment as regards position, time and depth of planting, suitable soil, &c.?—HOPEFUL ONE.

4174.—**The White Squill** (Scilla alba).—I want about 100 bulbs of this. I have enquired for it from several large nurseries without success. Unfortunately, many of our old-fashioned common flowers are now so neglected. I wish to plant it round a font for Easter decoration; also I wish to ask if any one can recommend any other flower tor the purpose?—LOVER OF FLOWERS.

4175.—**Moss on Garden Vases.**—Does it injure vases if Moss is allowed to grow on them? if so, how can it be removed?—OUNDLE.

4176.—**Snails on Ferns.**—We have some fine Maidenhairs, but nearly all the plants are infested with tiny snails in shells. What is the best way of destroying them?—E. S. S.

4177.—**Repairing Boiler.**—Will some reader tell me the best way of repairing a coil boiler made of 1-in. piping which has burst, leaving a small opening about ½ in. by ¼ in. where it is exposed to the fire?—LANCASHIRE.

4178.—**Hyacinths and Tulips for Exhibition.**—Will any one tell me when to place Hyacinths and Tulips in a temperature of about 55° for exhibition late in March? They were potted early in November.—J. B.

4179.—**Propagating Tree Carnations.**—When young plants struck this season have grown 9 in. or 10 in. high can the tops be taken off for cutting again without injury to the plant.—CANTAB.

4180.—**Worm Casts on Bowling Greens.**—Some firms in the north of England advertise what they term "their specially prepared ground charcoal" as an infallible remedy for clearing bowling greens of worms. Will any reader inform me what effect charcoal has upon the worms? and whether it is animal or vegetable charcoal that it used?—HOPE'S FRIEND.

4181.—**Plants for Windows in Summer.**—I have a window facing the east in Regent's Park which I wish to have some flowers in. I have two boxes to fit window ledge, one filled with Crocuses and Snowdrops, and the other with Hyacinths and Tulips. Will some one tell me what to grow after, so as to get the best show with moderate expense?—FUNNIDOS.

4182.—**Cleaning a Paraffin Cask.**—Will some one kindly say how a cask which was recently filled with paraffin can be speedily and thoroughly cleansed, so that the rain-water which it is intended to contain may be safely used for household purposes?—G. G. P.

4183.—**Liquid Manure.**—Will the liquor drained from a pig-sty when diluted do as manure water for greenhouse plants?—AMATEUR.

4184.—**Potatoes for Seed.**—Last spring I planted some Potatoes on heavy, damp ground, just dug and manured as they were planted. They are not fit to be eaten, as they taste strong of manure, and are watery Will they do for seed? I have had the ground manured and ridged.—J. S.

4185.—**Grafting Camellias.**—I am about to graft a few Camellias. Will any one tell me what would be the best stocks, and how long they have to be potted before grafting, and a few hints as to bring them on afterwards?—C. SAUNDERS.

4186.—**Earwigs.**—Will any reader kindly tell me how I can get rid of earwigs in my garden and house? The house has only been built six years, and has but a few small creepers on it. Still, during last summer, every room was infested by these insects, and every flower, and especially every Rose I gathered, was certain to contain two or three earwigs.—E. E. N.

4187.—**Petroleum Cask for Liquid Manure.**—I have an empty forty-gallon petroleum cask which I purpose using this season to hold liquid manure for a newly planted bed of Liliums. Will some one tell me if the lamp oil which must have soaked into the wood will have any injurious effects on the Lilies, some of which are rare and valuable kinds?—SAXON.

Small Vases for Flowers.—Charming arrangements of flowers can be made at this season with but few blooms, and those not of expensive varieties. A few days since I arranged two little vases, or rather specimen glasses, with the following: In each I placed a sihgle bloom of a double variety of white Azalea, some sprays of Deutzia gracilis, and three white Cyclamens, the whole being backed by a frond of Pteris tremula; two smaller fronds of this Fern were also placed in front, and bent down so as to group gracefully. These little vases were arranged to match, and were for placing on a side table in the drawing-room. Many pretty floral groups can be effected with but few flowers if a little time and taste be employed in their arrangement. The Dielytra is a flower now coming into the market, and is well adopted for the decoration of both large and small vases, as sprays can be obtained and cut off this plant of almost any size. This flower hos the advantage, too, of being equally effective by either day or artificial light. As a hardy plant the Pyracantha is very useful for cut purposes; a spray of it when placed amongst white oowers, such as Lily of the Valloy, Deutzias, &c., with the additien of a little Fern, being extremely effective.—A. H.

BEES.

Keeping Bees.—Many of the readers of GARDENING ILLUSTRATED will have heard or read of the poor clergyman that could not make both ends meet who applied to his bishop for assistance, who, after hearing his case, advised him to go home and keep bees. Whether he did so we know not; it is very certain he might have had worse advice. We hope that none of our readers are in this condition; but, be this as it may, we will, for other reasons than that of making both ends meet, advise all that can do so to take the good bishop's advice and keep bees. It will be a benefit to the nation and our neighbours, and pleasure and profit to ourselves. Bees, in addition to the honey they gather, greatly assist us in fertilising all kinds of fruit by going among the blossoms for honey and bee bread; therefore, more bees, more honey and more fruit of all kinds. What we as a nation pay for imported fruit may not be known, but it is known that we pay to other nations over £40,000 yearly for honey alone. A great part of this large sum might be kept at home by keeping more bees to bring in the ungathered honey from the fruit trees and flowers of the garden and field. People that dwell in the country or on the outskirts of the towns are in the best positions for the employment. A garden, yard, or field is needful to place them in. Some not having the one or the other hire for a small sum a garden or yard of those that will let them for the purpose. We are writing not for those who keep bees, but for those that do not, that they may be induced to do so, for if they care either for profit or pleasure, they will not find anything that will give it at so small a cost. In another paper I propose to advise how to commence bee keeping.—H. P.

Bees in Windy Weather.—The fanciful idea that bees carry little stones on their legs in windy weather doubtless arose from Virgil noticing the little yellowish lumps of pollen on the hind legs of the workers as they return to the hive. This pollen is the dust collected from the anthers of flowers and packed on the hind legs, which in worker bees are hollowed to receive it, and is the flesh-forming food of bees, while honey is the heat-giving.—A BERKSHIRE BEE-KEEPER.

POULTRY.

Care of Poultry.—The American *Poultry Yard* says:—We must now keep closed the doors and windows of our fowl houses to guard the occupants against the sharp air by day, and the chillier atmosphere at night. But let us be sufficiently careful to perform this operation sensibly, and not to stifle the birds that the emanations from their bodies will infect the internal atmosphere of the premises, and thus poison or sicken the stock. Ventilate the premises thoroughly every day and every night in the year. No matter how hot, how cold, how dry, the fresh air of heaven must be afforded your fowls, either by allowing them freedom out-of-doors altogether, or by supplying their quarters with this necessity to their comfort and thrift.

Pullets Losing the Use of their Legs.—I have recently found some of my pullets lying on their breasts and sides, and although they eat as usual, and appear otherwise healthy, yet they are unable to stand upon their legs; they are attacked in this manner in one night. I feed them regularly twice a day, and they have abundance of green leaves, &c., but have not much run, only about 12 ft. by 3 ft. Can any reader tell me the cause of these attacks, and what I can do to cure the bird? One of my best is now quit unable to stand.—TEACHABLE.

Fowls with Swollen Eyes.—I cured all my fowls of this disease the last twelve months with iodine. Apply carefully by jirking the bottle on the cork, and paint the swelling all over with the cork, so that none runs into the eye. Perhaps if applied with a camel's-hair pencil it might do so. Give the hen a Plummer's pill, and put her in a hamper all night, and the next day in the kitchen to keep her warm. Iodine the swelling four or five days, and then every alternate day until well, but do not let the eyes get sore, or the other hens would peck them. Before I tried this method all my fowls died, as the disease goes to the brain.—AMELIA SMITH.

Brahma Fowls in Small Spaces.—Will some reader be good enough to tell me how many Brahma fowls I can keep healthfully in the under-mentioned space: Hen-house, 5 ft. by 3 ft., and 3 ft. high; grass run 30 ft. by 6 ft. Also, is dry sawdust a good thing for fowls to have in hen-houses?—LEHO.

Scales on Fowls' Legs.—Can any reader inform me of the cause of a number of my hens having scales on their legs? also the cure, if any? and whether it is infectious?—POULTRYMAN.

Best Fowls to Keep.—I am thinking of keeping fowls; what are the best sort to keep? I want them good layers, and at the same time their appearance satisfactory. What do you think of Black Spanish and Brahmas?—F. C. W. K. [You do not say whether you want them for a confined space, or whether you have a grass run for them.]

Poultry Breeding for Profit.—As I am about starting poultry breeding as a means of profit, and by incubation, I should be very thankful for information as to class of birds for crossing to produce, size, quality, hardiness, and layers of a plentiful supply of large eggs, and if now would be a suitable time for commencing?—A CONSTANT SUBSCRIBER.

THE HOUSEHOLD.

How to Cook Haricot Beans.—If "Ferndale" will substitute the following for hi recipe on p. 542, I think it will be found to be a great improvement, and give to this dish an increased value amongst those who like a change from our ordinary vegetables. Well wash the beans, soak them twelve hours, put them in a stewpan, cover with cold water, and put them on the fire; when they boil up, put in a lump of salt and draw them to the side of the fire, where they must simmer (only) until the skins crack; strain off the water immediately, and cover up closely; have ready one or two onions (according to taste) finely shredded and fried in oil, butter, or good dripping to a nice straw colour; take off the lid of the stewpan, put in the fried onions with a little more butter, shake until mixed well, put into a dish and serve hot, previously sprinkling over a little fine-chopped Parsley.—EDMONTONIENSIS.

Tomatoes (Stewed).—Get a tin of American Tomatoes (cost 7d. or 8d.), cut off the top of the tin, put in a sufficient quantity of bread crumbs to absorb all the juice, and stand the tin in a saucepan of boiling water over the fire until the whole of the fruit is heated through; stir in 2 oz. of butter and serve. (N. B.—Mind the water does not boil over into the tin, and keep the lid of the saucepan off; condensed steam does not then drop into the fruit.—M.

Tomatoes *(au gratin).*—When the Tomatoes have been prepared according to the last recipe and are ready for dishing up, turn them out into any convenient dish, sift them over with bread crumbs, put into a Dutch oven before the fire until nicely browned, then serve.—EMONTONIENSIS

GARDENING ILLUSTRATED.

VOL. II.—No. 101. *SATURDAY, FEBRUARY* 12, 1881. PRICE ONE PENNY. REGISTERED FOR TRANSMISSION ABROAD.

BOUVARDIAS.

FEW plants are more easily grown, or more amply reward the care of the cultivator by the production of abundance of flowers than the Bouvardias, yet it is only with a limited number of growers that they are brought to perfection; and while those who are fortunate in this respect can bring them into flower during any month in the year, or have them in succession all the year round, the majority of those who attempt their culture fail not because they cannot grow them, but generally because they take too much pains with them in the wrong direction, such as keeping them in pots throughout the summer, and nursing them up under glass, whereby they are induced to make weak wiry wood and hard dry leaves, generally infested with insects. The chief point in the culture of Bouvardias, or, indeed, in that of any other class of plants, is to induce them to make strong, clean growth, and flowers will follow as a matter of course. Bouvardias should be treated according to the time at which they are required to flower, but they are most useful when in bloom in winter, a season when market growers contrive to have a large quantity of them in bloom. Bouvardias are popular plants in our flower markets, either the plants themselves or their blooms being offered for sale during the greater part of the year. For bouquet making the white-flowered kinds are especially useful; indeed, seldom is a bouquet made which does not contain some Bouvardia blossoms. The old B. jasminiflora still remains one of the best kinds for market purposes. Its dwarf, compact habit of growth, and its floriferous qualities, together with its easy culture, render it a favourite with everyone. One grower alone near London yearly disposes of from 20,000 to 30,000 plants of it; others grow it more for its blooms, and in that case it is grown in larger pots. The only scarlet-flowered kind grown to any extent is B. Hogarthi, which in habit resembles B. jasminiflora; it produces abundance of bright blossoms which are very effective amongst white flowers. For spring-flowering, a large white-flowered kind named B. jasminiflora corymbiflora (the large flower at the top of the above illustration) is grown to some extent. Its flowers are deliciously fragrant and much larger than those of any other kind in cultivation. Its chief value, however, is its blossoms in a cut state, for the plant is too rampant a grower ever to become a good market plant; only bushy little plants in 6-in. pots laden with blooms find favour in Covent Garden. Messrs. Beckwith & Sons, of Tottenham, however, have lately shown us some wonderful examples of this Bouvardia in 5-in. pots; they were indeed such as any cultivator might feel proud of. The difference in the plants of Bouvardias as seen in Covent Garden and those met with in private gardens is very marked. Country growers, as a rule, use the knife too sparingly in the case of Bouvardias, and, therefore, instead of dwarf bushy specimens clothed with healthy green foliage down to the rims of the pots, as seen in the market, we find long, spindly plants with miserable-looking, shrivelled-up leaves, and a few solitary sprays of flowers. We do not mean to say that all grow such miserable plants, but, as a rule, few good ones can be found in private gardens. The largest cultivators of Bouvardias in pots grow them as follows: In autumn old plants which have done flowering are cut down, nearly close to the pot, and placed in a moderately cool, dry temperature. After Christmas a little more heat is given them, and they are frequently syringed overhead; this has the effect of starting into growth a number of shoots from the bases of the plants. These, when sufficiently

GROUP OF BOUVARDIAS.

firm, are taken off, made into cuttings, inserted singly in 3-in. pots, and plunged in Cocoa-nut fibre on a gentle bottom-heat. These cuttings, under favourable circumstances, soon strike root, when they are potted in 5-in. and 6-in. pots in good fibrous loam and leaf-mould or rotten manure. As they advance in growth they are subjected to a cooler and more airy temperature than that in which they were struck, and when well established all the light, air, and sunshine possible are admitted to them, and they receive copious supplies of water at their roots. From these plants cuttings are taken with which to form a successional batch of plants; they are taken off when the plants have made three or four leaves, the two lower joints only being left on the plants. From these joints strong shoots are soon emitted; these when 4 in. or 5 in. long are also stopped, and this operation is carried on in the same manner for four or five times, each set of cuttings being treated in the same way. Those struck first in the year make excellent bushy flowering plants by the following autumn, and the last taken off, which is in August and September, make good plants to bloom in the succeeding spring. The old plants, from which the cuttings were first taken, are also shaken out and potted, and they make bushy, well-flowered plants early in the summer. In order to make large specimens, which, however, is seldom done in market gardens (except for supplying cut blooms), old plants are cut back year after year and shaken out and re-potted. During summer Bouvardias are grown in cool houses or pits, and sometimes in temporary frames, but in autumn, winter, and spring a moist, airy temperature of from 50° to 55° is maintained, excepting in severe weather, when a little lower temperature does not injure them. During late years some growers plant out their Bouvardias in the open air in summer, a plan by which good plants may be obtained with less labour and expense than in the case of those grown in pots. It, however, becomes a question whether they are so valuable to the buyer as well-established pot plants, but that, with growers for market, stands for nothing. For planting out cuttings are inserted early in February, stopped in the same way as before mentioned, and, after being duly hardened off, are planted out about 2 ft. apart in well-prepared ground the first week in June. During summer they are kept well supplied with manure water, the surface soil is kept well stirred with the hoe, and sometimes a mulching of manure is applied. In the first week of September, when the shoots show bloom, the plants are carefully lifted and potted, and, after being well watered overhead and at the roots, are placed in cold frames, and kept close and shaded until re-established; after that they are again exposed to air and sunshine, and when the weather gets cold they are placed in houses or warm pits near the glass. By this means strong, bushy, well-flowered specimens are obtained during the winter months which need no staking or support in any way. Indeed, under no circumstances do market growers stake Bouvardias, beyond placing a neat deal stick in the centre of each plant, so as to support the branches in a manner to form neat, but by no means formal, conical or pyramidal-shaped plants.

If Bouvardias are required for blooming in summer, a portion of the plants potted in the winter should be shifted into a size larger pot in the spring and kept growing. Although Bouvardias may be grown to perfection in an intermediate house, some of them, such as B. longiflora, B. jasminiflora, and B. Humboldti corymbiflora, will even stand stove temperature and flower beautifully; but where much heat is given care should be taken to ventilate freely. To Messrs. E. G. Henderson & Son, from whose establishment were obtained the flowering sprays from which our engraving was prepared, belongs the honour of having raised or introduced the greater part of the best Bouvardias in cultivation, and from these has been made the following selection, viz., B. Vreelandi or Davisoni, white; B. Hogarth, scarlet; B. elegans, bright scarlet; and B. Maidens' Blush, pale rose. These four belong to the same section, and are the very best for outdoor summer culture. B. Queen of Roses, rosy-pink; B. longiflora flammea, pale vermilion; and B. candidissima, snow-white, belong to an intermediate section, and form beautiful compact plants for winter blooming when grown in the open garden in summer. To these may be added B. Humboldti corymbiflora, white; B. jasminoides, white; B. umbellata carnea, white changing to blush; and B. flavescens, pale yellow. Occasional sprinklings with weak Tobacco water in the evening are the best means of keeping Bouvardias free from insects.

Arrangement for Flower-stands in Spring.—It is surprising how pretty we may have our windows and flower-stands in the early spring time, when there is such a scarcity of everything except bulbous plants; still, with even these they may look as gay as in the widst of summer by a little judicious management and arrangement of colour. Presuming we have a small stock of evergreens, such as Palms, hardy Ferns, miniature shrubs, Mosses, &c., to intersperse amongst the flowers, we can form a very pretty window or stand in tiers of different bulbs, putting the largest shrubs and Palms with the tall growing plants in the bottom, and the second tier might be composed of coloured Tulips in variety, and the two upper ones would look well filled with smaller Ferns and Mosses, with several pots of purple, yellow, and white Crocuses in between. Of course, I am omitting the more tender plants from the above arrangement, as the Chinese Primulas, Cyclamens, Cytisus, and many others; these may be substituted for the others, and the stands made even prettier and lighter looking, but these flowers do not bear the dust and close atmosphere of rooms as well as the hardy bulbs.—W. A. G.

Preserving Blooms of Chinese Primulas.—I think I have found out a secret for keeping cut blooms of Chinese Primulas in a good state of preservation in water. Having always proved that these flowers faded and drooped at once when cut, I gathered some blooms of the red and pink varieties, and placed them in fresh water in a room without a fire. This was about three weeks ago, and only yesterday (January 12) did I empty my vase of flowers. During that time they kept beautifully fresh, and looked as gay and bright as possible. Some of your readers will, I am sure, like to know this fact, and as the Primula is a flower well worth cutting for house decoration, we need not be afraid of seeing our blooms drop off in a few hours (as they most assuredly will do if placed in a warm, close temperature) by trying this simple plan, which is not as new to others as it is to me.—W. A. G.

Acacia lophantha.—This is a plant of singularly graceful habit and outline, and one that is particularly well adapted for windows, as there it shows off its elegant foliage to the greatest advantage. Not only is it good for either of these purposes, but it forms an admirable relief to the flatness and general uniformity of others on a stage when set so as to show clear above them; and half-a-dozen used in this way do much to give a finished look to any house in which they may be used. By sowing annually in spring, plants of this Acacia may be had with straight, single stems furnished with leaves down to the pot, and when in this condition they are exceedingly ornamental. The seeds, being somewhat hard, are rather slow in germinating, but in this they may be hastened by soaking them for twelve hours or so in warm water, after which they should be sown in sandy soil and placed in a Cucumber frame or warm greenhouse. A rich, light loam suits them best to grow in, and 6-in. pots are quite large enough for the first season, but if extra-sized plants are required they may be had by liberal shifts and feeding them well with manure water.

Camellias and Orchids.—These are well cultivated in the same house in a garden we lately visited near London. The Camellias occupy a back border of a narrow lean-to house, and are tied and pruned in, so as to form a sloping bank of glossy leaves and blossoms from the floor to the roof. The Orchids, which consist of Odontoglossums, Oncidiums, Cypripediums, Lycastes, &c., are grown in pots arranged on a narrow, gravel-covered stage along the front of the house next the glass, whilst from the roof are suspended noble plants of the snowy white-flowered Cœlogyne cristata growing in large, raft-like teak-wood baskets. Of Odontoglossum Alexandræ and O. Pescatorei and Lycaste Skinneri there is also a good display.

VEGETABLES.

HOW TO GROW PARSNIPS.

Parsnips do best in a deep, loose, not over rich, or at least not recently manured, soil. If manure be used at all, it should either be buried deeply, or be of such a nature that it will easily blend and mix with the soil. I have never found any disadvantage to arise from the moderate use of artificial manures, or soot, lime, salt, or any other substance of a similar nature whose tendency it is to become quickly absorbed and distributed in the land; always, of course, supposing the land required such aids, and that is a question which must be left to individual judgment. Parsnips in garden culture are a good successional crop to autumn Cauliflowers or Broccoli, or, indeed, any crop that can be cleared off before Christmas to give time for the thorough preparation of the land. This is a matter of the greatest importance for root crops.

A soil that has been deeply worked and freely exposed to the fertilising and enriching influence of the atmosphere is immeasurably superior for all root crops to ground that has lain dormant and sealed up through the winter, but it should not be worked when the surface is wet, as land, especially if of an adhesive nature, if trampled when wet takes a long time to recover its natural tone, such as the roots of plants delight to spread in. From the middle of February to the middle of March—according to season and locality—is the most suitable time to sow Parsnips, selecting a time when the soil is in good working order, for to put seeds of this kind into the land in wet weather is usually the prelude to an indifferent crop. Sow in drills 1 in. deep and 15 in. apart, and thin out the young plants to from 6 in. to 9 in. apart in the rows. The more space the plants are given, the larger the roots will grow; but large roots, except for some special purpose, are not always the best for the table; nor will they in all cases give the best result in bulk of crop according to the area of land occupied. The most useful crop is composed of regular, medium-sized roots, and these are more likely to be secured by thinning moderately. As soon as the young plants appear, run the Dutch hoe through the spaces between the rows to break up the crust; and in a few days draw a small-bladed hoe through the drills, leaving the plants in small patches 6 in. or so apart. In another week or ten days they may be singled, drawing out all weak plants.

This is a better plan than singling out at the same time the hoeing is done, as removing at one operation all the shelter which near association with each other has given them sometimes checks and retards those that remain, especially if the weather be cold. Frequent stirrings of the surface soil until it is covered with the growth of the plants will be exceedingly beneficial, and cannot be overdone. The frost in our climate is not severe enough to injure Parsnips, and it is a common practice to leave them in the ground till after Christmas; but they keep equally well if taken up in November and pitted as Carrots, Beets, &c., commonly are, and it gives an opportunity for getting the land prepared for the next crop in good time. I do not know how it is, but Parsnips have never received the attention they deserve, either as a garden or field crop. They are very nutritious—more so, I think, than either Carrots or Turnips; they certainly occupy the land rather longer than the latter, but that is scarcely a disadvantage, and could easily be managed in arranging the rotations. I certainly think they would pay the small occupier who kept cows, for stock of all kinds (including poultry) eat them readily; and they do not, when given to milch cows, impart that disagreeable taste to the butter that Turnips do. They are much less subject to insects or diseases than most other crops, and seldom or never fail in producing a good crop on well-prepared land. Four pounds of seed will be sufficient for an acre, and, if labour were scarce and dear, by having the drills a few inches further apart, most of the surface stirring and cleaning of the land could be done with the horse hoe; and in field culture they come in well in place of Potatoes or Carrots for a change. H.

Indian Corn.—I observe in Gardening Illustrated a remark about Indian Corn grown in the garden. I have seen it grown, and grown it myself for the last forty years. To do so, successfully, however, it is necessary to get the right sort. For many years I had lost this, and by mere accident saw an advertisement in a newspaper stating where the true seed was to be found, and recovered it—"Cobbetts's Indian Corn." It is of very short growth, and I suppose it is thoroughly acclimatised, as with this seed I never fail, and now take care to keep plenty in reserve. Having been brought up by old Indians, I learned to delight in the fresh corn "cobs." The seed should be sown in the beginning of May, in the open ground, on highly manured ridges. A quantity should also be sown in a box under glass, so that there may be a supply from which to prick out plants to fill up vacancies in the rows. The plants, when they begin to grow vigorously, should be slightly earthed up, and when coming into flower should be in some way supported by strings or stakes. As soon as the female trusses appear to be fecundated, and turn slightly brown, I cut off the flower. I never trust anyone to gather the "cobs," as there is a critical moment when they are fit for the cook, and a day or two too soon or too late is fatal. To send them up to table, boil them in milk for an hour; then "broil" them, basting with cold butter and lots of pepper. Be regardless of appearances, kneading them between the fingers, and a more delicious dish is never put upon the breakfast table. —Frederic Fane.

Vegetables in Succession.—In keeping up a regular supply of vegetables there are two matters especially important; the first is to sow or plant the right kinds at the proper seasons for succession, and the second is to sow or plant just the right quantities. For instance, in the case of Cauliflowers, Lettuce, or any other crop that is apt to bolt prematurely, or, at any rate, is much influenced by the seasons, sowing little and often should be the rule, at the same time taking advantage of the various aspects of the garden to suit the different crops to the varying seasons. There is no doubt that the majority of kitchen gardens are too much shaded and sheltered by fruit trees. The best vegetables are invariably produced in the large open spaces where the air can freely circulate amongst them. A warm sunny spot under a south wall is a very desirable place for early crops, but the wants in this way are small in comparison with the requirements of the whole year. In a maggot-fested garden there should be no main crop of Carrots, but, instead, a regular succession of sowing monthly from the forced crops under glass in January till the last sowing of Early Nantes to stand the winter in the border in the first week in August, and which can be sheltered in very severe weather with a sprinkling of dry, loose litter. Good sweet young Carrots can be had all the year round in this way without taking up more land or costing more than if the main-crop sowing had been relied on for a good part of the year's supply; and even where a clean crop free from maggots can be grown, the old roots lose flavour before the young forced crop comes in, and the plan of sowing small successional crops will be found more satisfactory. In a less degree the same remarks apply to Onions. Where the maggots are troublesome the autumn-sown crops generally escape their attacks, and this fact should lead us, if we have any doubt of our soil, to sow at least a good half of the year's supply at that season. A rough plan of the kitchen garden is a great advantage in working out the season's work; it should be drawn to scale, and the crops now occupying the ground marked on it. The more a subject is thought over the easier and simpler it becomes, and if a thing is often present in the mind fresh lights are constantly breaking in upon us, and I suppose no one is so perfect in anything as to escape the necessity for wishing or trying to improve.—H. R.

Savoys.—Where bulk rather than quality is the object sought, sow Drumhead early in March, and plant out in June in drills, 2 ft. apart and 20 in. in the rows. But for garden culture, where delicacy of flavour is appreciated, plant the smaller kinds, such as the Dwarf Ulm, Marcellan, and King Koffee. The latter is a delicious vegetable, very tender, and less coarse in texture than the larger kinds; although small, it may be planted so much closer together, that after all it will be found to be a profitable crop. Sow in March, April, or May, according to the time the crop may be required; and it is a really good plan to sow a few seeds in each month, and put out a few plants at intervals in any convenient spot from May to August. Planted in rows 1 ft. apart and 9 in. in the rows will be ample space between.

Winter Salad Plants.—Witloof is highly appreciated with me for salad. We took the roots up in October, and they were treated the same as Carrots. When put into the Mushroom house the tops soon blanch, and when mixed with Endive make a good salad; nor are they to be despised when cooked like Seakale and used as a vegetable. The Improved Round-leaved Endive has proved the best with us; blanched out-of-doors under small Seakale pots, or placed in boxes in the Mushroom house for a few days, a good salad may in this way be had by all, even where glass is limited.—J. A.

PASSION-FLOWERS.

These, on account of their singular beauty and the associations connected with them, are popular plants with most people. Passiflora cœrulea, the hardiest and best known, is a pretty variety which grows and flowers freely on open walls, and in favourable situations ripens its fruit. It does well between the gables of two lean-to glass houses, for example, or on the sheltered end of a cottage with a fire behind it. It likes a moderately light, rich, loamy soil, and if the roots be enclosed on all sides with slates or flags, and not allowed to get down too deeply, they will be much more favourably situated as regards temperature, watering, and general culture than

Spray of the Hardy Passion Flower (Passiflora cœrulea)

they otherwise would be. How to train it is a consideration, and the simplest plan is the best. It is a mistake to nail the shoots up or across the wall, as is usually done. If the wall be not very high, lead the main limb up to the top direct at the beginning, and then along the top just under the coping. Most likely it will throw out side shoots as it grows; but if not in sufficient number, occasional pinching will make it break more freely. The shoots should simply be allowed to hang down on the face of the wall without tying of any kind, and a very graceful drapery they will make, either with or without flowers, but flowers are sure to be produced in quantity. The extension system of training is the best in the case of Passion-flowers. We have seen a lofty-fronted glass structure, 70 ft. long, draped from end to end with them in the manner just described, the shoots being allowed to fall 9 in. apart. Two plants furnished the whole, one being planted out at each end.

The culture of greenhouse varieties is pretty much the same as for the hardier kinds. In all cases it is well to confine the roots in a stone box, from 2 ft. to 4 ft. wide, according to the area which the plant has to cover. If practicable, train also in the same way. Take the shoots along the roof in a methodical manner, but let their extremities hang down here and there in order to bring their flowers within reach, and to give the plant a natural aspect. If the roots be well drained, water freely and

otten, as they soon fill a large box, and get as matted as in a flower pot. Top-dress, too, annually or periodically with rich soil, and additional root-room will never be required. I once had a plant of P. edulis which bore a heavy crop annually for many years, the roots all the while being confined to a box 20 in. square. During the growing season the knife must be used freely in order to remove entirely the shoots where they are too crowded; and when the plant ceases to grow and flower as winter approaches, it should be pruned well back to the old wood.

Stove varieties, such as P. Buonapartia and quadrangularis, may be treated the same as the greenhouse sorts when grown for the sake of their flowers, but if fruit be the object, more careful and slightly altered treatment is necessary. P. quadrangularis and P. edulis are the two kinds that are most esteemed for their fruit. The first is the large and now pretty well-known Granadilla, and the second has fruit about the size of a pigeon's egg, purplish coloured and the more ornamental of the two, but both form an agreeable addition to the dessert. I have had fifty or more half-pound fruits on a plant of the Granadilla which was struck from a cutting the previous autumn. Cuttings of the young points should be struck in summer or autumn, and early in February they should be planted out in a 20-in. pot or tub, in a good compost of loam, leaf-mould, and manure, and plunged permanently in a bottom-heat of 85° or 90°. As the shoots grow rapidly, they must be prevented from becoming entangled, and be trained within 1 ft. of the glass, and never stopped on any account. If they get

Spray of the Water Lemon (Passiflora laurifolia.)

crowded, remove some of the shoots entirely, but allow those left to grow on uninterruptedly. About midsummer flowers will be produced towards the extremities of the shoots, and they will continue to appear afterwards at almost every joint; as they expand daily, they must be fertilised with a camel's-hair brush, or they will not set. Maintain a moist and high temperature throughout the growing season; 75° by night and 90° with sun-heat will suit them well. When the fruit begins to change colour, diminish the moisture a little, but at all times keep all the supply at the root, for the abundant foliage makes a great demand upon the roots, and if water be not supplied in abundance the fruit will drop, especially in the early stages of its development. About November, when it is all gathered, prune the shoots hard back, and keep the plants still, but moist at the root, all the winter.

Almost all the varieties are subject to red spider and mealy bug; but generous culture and a vigorous application of the syringe will generally keep both these pests in subjection. The best stove kinds are P. amabilis, Beloti, kermesina, edulis, princeps, quadrangularis, and Buonapartia; the greenhouse sorts consist of Innesi, Impératrice Eugénie, racemosa, cœrulea, and Campbelli. P. laurifolia, which we now figure, bears sweet-scented red and violet flowers. The fruit, which is yellow, is lemon-shaped, and about the size of a hen's egg. It is sometimes called the Water Lemon. S.

Early Forget-me-not (Myosotis dissitiflora) **for Pot Culture.**—The value of this charming little Forget-me-not is much enhanced when it is brought into bloom some weeks earlier than it flowers naturally in the open air. Our springs are not always kind to this little plant, for just at the time when it is coming to cheer us with its profusion of bright blue flowers, its progress is rudely stopped by frost, biting winds, or ungenial weather of some kind. It may be had, though, and early in the year in all its charming freshness of leafage and beauty of bloom with but a slight amount of labour to the grower. All that it needs is just sufficient protection during the winter to ward off extremes of weather. What injures this Forget-me-not is alternations of freezing and thawing, snow filling up the crown, partially melting, and then congealing into a solid mass of ice. The comparatively tender tissues of the flowering stems give way under such a severe trial, and blanks and discoloured leafage occur where verdure and floral beauty should reign. There is no more lovely little plant than this for the embellishment of the conservatory in early spring; it equals, or even surpasses, the Lobelia in effect, for the blue of the flowers is lovely in the extreme, and is never seen to so great advantage as when in intimate association with other shades of colour. Sow early in the summer, grow along freely, pot up in autumn, and protect against severe weather, and you will have in early spring floral gems of the first water and such as will not be misplaced wherever and whenever employed.—J. CORNHILL.

Eupatorium odoratissimum.—This is a very useful plant for winter blooming. It is invaluable for the cool conservatory, and is especially suitable where means are limited. We have a number of large bushes of it standing in a house where the frost has only just been kept out quite white with large panicles of flowers, and they have been in this condition for the last six weeks, and will continue so for a long time yet, and after the first bloom is over, if the ends of the shoots are cut off, a new crop of flowers will be produced. The plants to which I am referring were old ones cut hard back last June, planted out in an open sunny border, lifted and potted in September, placed on the north side of a fence to get established a little, and housed before sharp frost was expected. Cuttings struck in spring and planted out will make good-sized bushes in one season, but do not, of course, make such dense, well-furnished specimens as older plants that have been well pruned in and planted out about June.—E. R.

Heliotropes in Winter.—When the stock of Heliotropes is propagated for bedding in spring, a few dozen of the most vigorous plants should be selected, and grown on specially for winter flowering. They should not be allowed to starve in small pots, but should be shifted into larger pots before they receive any check, and as soon as all danger from frost is over they should be plunged in a bed of cold ashes up to the rims of the pots in the open air. All shoots should be pinched back, to induce a bushy habit, and by so doing flowers will not be permitted to form. The bed should occupy an open situation, and the plants must stand far enough apart individually to permit of a free circulation of air, and so insure robust, short-jointed growth. Such plants when placed on a shelf in a warm intermediate or forcing house in winter will produce a large number of flowers for cutting from October to February or March. Good little bushes may be had in 5-in. pots, but the strongest will require a size larger. Plunging the pots in summer will save watering, and prevent the hot sun acting so forcibly on the roots at the sides of the pots, from which cause plants that are standing far apart with their pots unprotected sometimes lose their leaves. A few of the most vigorous may, if desired, be trained as standards, with stems 12 in. or so long. By attention to pinching good bushy plants may be had in one season. The dark purple-flowered varieties are the best for winter blooming, as the pale-coloured flowers become still paler in brisk heat, but the dark varieties still retain a delightful tint of purple. Heliotrope flowers may also be had in abundance in winter from old plants planted out and trained against a wall in a warm, light house—indeed, that is the best plan to adopt if the flowers are wanted in quantity The plants should be pruned well back about the end of August, or a little earlier or later, according to the time the flowers are required. The syringe should be used freely, to induce a free and vigorous break; but when once the shoots have fairly broken into growth less syringing will be required, as this, as autumn approaches, only tends to promote weak growth. After a good break has been secured, the size and number or the trusses of flowers will be in proportion to the direct light that reaches the plants, accompanied, as it should be, by a corresponding amount of heat.—R. A.

Highclere Pink.—This is one of the best rich crimson-scarlet Pinks we have for borders. It keeps long in bloom, and it is equally good for forcing as for outdoor decoration. Some plants of it struck last spring are just now coming into bloom, and promise to produce flowers in abundance.—J. C. F.

Ficus radicans.—This makes an excellent plant for baskets, or, when grown in pots, it is very useful and effective for draping the path walls of plant-houses. It grows rapidly, and will withstand a great amount of rough usage, and is therefore well adapted for room decoration. It is a plant not very commonly met with, but it is largely grown by a few nurserymen near London, who carry out indoor decoration on an extensive scale.

Double-flowered Plum (Prunus sinensis fl.-pl.).—Amongst winter-flowering conservatory plants one of the prettiest at present is this double white Prunus, and it is a plant that requires but little heat to bring it into flower. Every shoot of last season's growth is now laden with most beautiful pearly white double flowers, and they remain in good condition for a considerable time in a cool conservatory temperature. I find this, Deutzia gracilis, and Spiræa japonica to be most useful for mixing with brightly-coloured Azaleas and Dutch bulbs now coming freely into bloom.—J. G. L.

How I Grow Tuberoses.—The fragrance of the flowers of these is not surpassed even by that of the Gardenia; indeed, it is much more agreeable, as Tuberoses have not that sickly odour about them which the Gardenia gives off when one comes too near it. Besides, the flowers are quite as beautiful, last longer, and can be used for similar purposes, and last, but not least, the plants are easily grown, and are not troubled with insects. The imported roots are the best, and should be potted as soon as possible, at least for early work. A noteworthy authority on the subject recommends the plants to be plunged in strong bottom heat as soon as potted, and afterwards grown on in cooler quarters, but they do quite as well if started gently and pushed on leisurely. One lot was potted last year in February, rather late in the month, and started in an intermediate house, but the pots were not plunged. The plants started into growth sooner than was expected, and to prevent the leaves and stems from becoming soft and lanky they were moved into another house, where they got plenty of light and air and a place for themselves, and throughout the summer and part of the autumn no artificial heat given, but the house was kept warmer than a greenhouse. They made robust growth, but very tall stems, and did not flower till August, and they continued to produce flowers for about three months. Later in the autumn a little heat was given to assist the development of the flowers. As it was just the season we need such flowers, most single flowers were cut every day, and a number of the plants were placed in the conservatory to give fragrance to the house. The Tuberose is best grown in single plants to a pot, and 6-in. pots are a suitable size. A compost consisting of three parts loam, one part peat and sand, and a little well-rotted manure will suit well. Good drainage, but not too much of it, should be afforded, and during growth plenty of water should be given.—W.

SHOW AND FANCY PELARGONIUMS.

The varieties of Pelargonium best adapted for the requirements of the grower for profit and decorative purposes, whose principal object is to have plants that will produce large quantities of bloom, and that will be as much as possible continually in that condition—in fact, kinds that may be had in flower at almost any period of the year, are very different from the kinds grown expressly for exhibition. They must be robust, and have flowers of brilliant and striking colours and large in the trusses, with individual flowers of good substance. The form of the blossom is not so much considered as it is in the case of florists' kinds strictly so called, but many of these are truly beautiful, and almost equal in form to that of the so-called florists' kinds. In many private gardens there is to be found a greenhouse that could be devoted with the greatest advantage to the culture of these truly useful and really beautiful plants, and I would recommend intending growers of them to visit Covent Garden in the spring in order to make a selection of the best and most striking kinds. This is the best way by far of forming a collection, as one sees what one is buying in its true character, and thus mistakes are less likely to be made, and time, which often is wasted in cultivating an indifferent selection, is saved. The little additional money expended in purchasing the best kinds to be obtained in the first instance is in the end the truest economy. When the plants are bought, the grower will furnish the names of the sorts, which can be cheaply packed in common Orange boxes. The latter are easily procured in the market, and very largely they are used for such a purpose. Place the pots closely and tightly together, and they will travel any distance in safety; they do not require any covering, provided, of course, it is not frosty. Almost all the pot plants that go from Covent Garden to the large northern towns of England are despatched in this simple and expeditious manner. As soon as the plants have reached their future home, cut them down and begin propagating them at once, as these kinds—unlike the sorts grown for purposes of exhibition—are best struck as soon as possible in the season, and in a soft, green state; thus treated, they will always be vigorous and clothed with healthy foliage to the pots. This matter of early propagation is indeed absolutely essential, because the plants are required to be perfect little specimens the following spring. It will therefore be obvious that there is no time to be lost. When the cuttings are made in the usual manner, about four or five may be inserted in some good sandy soil round the edges of a large 3-in. pot. I have found this plan better than larger pots filled with cuttings, as when crowded, at the time of potting off the majority of the roots get broken and the young plants receive a severe check; whereas in the smaller pot and round the outside the roots can be easily preserved, and the young stock receives no check. Use pots that are perfectly clean, otherwise when you wish to repot your plants you cannot do so without injuring the roots, which adhere to the sides of the dirty pot. Place the cuttings when inserted in a house near the glass, sprinkle them with water, and shade them if the weather is bright, as green cuttings should not be allowed to flag. Look sharply for green fly, remove decaying foliage, and the cuttings will soon strike root, and be ready to be placed singly in small 2-in. pots.

Show and French Spotted Pelargoniums.

Treatment after Potting.—As soon as the newly-potted plants have taken hold of the fresh soil they must receive their final pinching in, and be encouraged to grow in every way, treating later stock in a precisely similar manner. Be sure not to overcrowd. The temperature should be about 50° minimum, with ventilation night and day. During the dull winter months avoid as much as possible wetting the foliage when watering, and only give water when the plants are dry, and then a thorough soaking should be administered. Nothing can be worse for plants of all kinds than homœopathic doses of water thus given. The surface of the soil often appears moist when in reality the roots beneath are suffering from drought. Be careful, therefore, that this important operation is at all times properly performed. By January the earliest plants will be fast pushing up their flower-buds, and will require tying out to a few neat stakes, of which, however, as few should be used as possible, consistent with a due regard to the form of the plant and prevention from breakage. Use liquid manure freely. Let the temperature increase 5° or 10°, according to the state of the weather, taking every possible advantage of sun-heat; thoroughly cleanse the foliage (of which at all times the greatest care must be taken) by the free use of the syringe and plenty of clear rain-water, and also fumigate frequently with Tobacco, in order to kill that bitterest insect foe with which Pelargoniums have to contend against, viz., green fly. As the plants approach the blooming stage, provision should be made for shading them when necessary, and, of course, for the exclusion of bees. When the month of March has set in, the grower, if all has gone well, will be in possession of a house full of about as useful and beautiful plants as can well be imagined.

The Fancy Pelargonium requires in all its management treatment similar to that of the large-flowered kinds, with this exception, that, being naturally more feeble in constitution, it requires a rather lighter soil to grow in and more warmth. They require also special care in watering; if once this is overdone death is the inevitable result. The fancy Pelargonium thrives remarkably well when grafted on strong-growing stocks of the large-flowered varieties.

Best Description of House.—The best structure for their growth is a low, well-ventilated, well-heated, span-roofed greenhouse, with a path down the centre, and stages or beds of a convenient width on either side. Do not have the shelves too wide; nothing is gained by that, as, of course, the easier the plants can be reached in order to clear them of dead foliage, or to tie and water them, the better and more expeditiously can these operations be performed. Keep them a little close for a few days after potting, and see that they are thoroughly soaked with water at first. When established, give them all the air and light available, and of course as the summer weather sets in no artificial heat will be needed. Pinch out the points of the shoots to induce a dwarf bushy habit, and shift into a size larger pot as soon as convenient. Some place their stock of young Pelargoniums out-of-doors in summer, but with this plan I do not agree, as the foliage becomes rusty, and in a great many cases the foundation of a bad attack of spot is laid. Therefore, keep them under glass, and allow them all the ventilation possible, and no shading. A good plan by which the excessive use of the watering-pot may be avoided in very hot weather is to cover the stages with old mats, and place on them about 2 in. in thickness of coal ashes or Cocoa-nut refuse. Upon this set the pots, and the plants will be greatly benefited thereby. By the end of August, the plants for blooming in the month of March should be in their flowering pots, 5-in. or 6-in. ones—not larger. Use rather heavy loam for them, and not much decayed manure and sand. When such small pots are employed the soil cannot well have too much substance in it, and it must not be pressed down too firmly Pieces of soft red bricks—a material to which the roots are very partial—make good drainage, and as brick is a naturally cool substance and retains moisture, it is very beneficial to the plant at a time when they most want such assistance. Therefore use for drainage broken bricks in preference to the ordinary potsherds. The remaining portion of the stock may be repotted, say in September for blooming in April, in October for May, and immediately after Christmas for flowering late in June and July. In this way a good fresh supply of plants will always be available for decorative purposes.

H. B.

LAW RELATING TO GREENHOUSES.

I see this subject is again to the fore. Previous communications have escaped me but I observe that "P. G. C." argues for green houses being included in the "buildings' of the Metropolitan Building Act. As you may remember, this question came before the courts some time ago in the case in which I was defendant—Turner *v.* Norris—and I thought that the position of greenhouses had been definitely set at rest, in the contrary sense to that for which your correspondent "P. G. C." argues. This, however, does not seem to be the case, and by your permission I will recapitulate the salient features of my case, which may again perhaps altogether settle this debateable subject.

I built my greenhouse the width of my garden 17 ft. and 4 ft. deep by 17 ft. high. It was built so as to be a tenant's fixture—*i.e.*, without being fixed to the wall, although fitting thereto closely; the front of the house was of plain panels about 3 ft. high, and from that height and above the walls, 3½ ft. high, all round and at top was glass work. I had a stove in the house into an iron pipe flue. I had intended to board over the walls within the greenhouse, but at the time of the action this had not been done; hence the descriptions of the surveyor to be after-mentioned. The district surveyor came down upon me first on one and then on a second act, with the command to re-build the house with 9-in. brick walls, certain foundations and several other injunctions (I quote from memory), but in particular a slate roof (!!). Having had 40 years' experience of house property, I gave this man's instructions that attention which they deserved.

After certain delay the surveyor summoned me before the Clerkenwell Police Court, in the summons describing my greenhouse as having, beside wood and glass, &c., certain brick panels (alluding to the walls of the garden which I had not yet covered in). There were also references to the stove and parts in the Act relating to all were indicated. I employed an able solicitor, Mr. Ricketts, who successfully carried the case through, grounding his case on the clause relating to exempted buildings, among which "greenhouses, party walls," &c., &c., are mentioned. The judge having been satisfied that the house was solely for the keeping and rearing of plants, decided that it was

exempt. The surveyor strove for the "flue and chimney clause," but the judge decided that only had reference to dwelling houses. We gained the day completely. The judge described the prescription of a "slate roof" for a greenhouse as absurd. The injunction about 9-in. walls, &c., the judge said related only to dwelling houses. The brick panels of which the surveyor sought to make a "damning clause" were covered by the surveyor's own confession that they were party walls; and moreover "party walls" also were exemptions of the Act. We won the victory for the exemption of greenhouses at the cost of 30s., our own costs only—just 30s. fine for the incompetency of a public servant.

Mr. Ricketts declared my case was the first of its kind and would form the precedent for future cases. Therefore it will be of importance for anyone in future troubled with any of these functionaries to communicate or refer their legal adviser to this gentlemen as to the case. One or two remarks may be made on the foregoing: 1st, greenhouses are exempt; 2nd, greenhouse stoves and heating apparatus, flues, &c., are also exempt. Then remains the question of nearness to other buildings qualifying the above. The limits of distance are mentioned in the Act — 1st, a greenhouse flue leaning against a dwelling house might be objectionable (see limits of distance); 2nd, a greenhouse of an abnormal size might fail under some section as to safe building. (See limits of size). It being always understood that these Acts are enacted to safeguard life and limb from fire or insecure structures, not to afford sport for certain officials, and the limits and bounds of these can be readily judged by any ordinary individual. F. Norris.

THE COMING WEEK'S WORK

Extracts from a Garden Diary.

February 14.—Digging land for Cabbages and Cauliflowers. Sowing Sweet Peas. Sowing Fulmer's French Beans in pots in heat. Sowing Radishes out-of-doors. Sowing Radishes in frames planted with sprouted Potatoes. Sowing Onions and Leeks. Potting off plants of Oxalis; also Chrysanthemums, and placing them in cold pits. Shifting a few Ten-week Stocks into 6-in. pots. Pricking off Viola cornuta; also spring-sown Cauliflowers in frame. Putting in cuttings of Bouvardias, Fuchsias, scented Pelargoniums, Verbenas, and Dracænas. Getting baskets for conservatory planted with Nemophila, Saponaria, Musk, and Creeping Jenny. Planting Globe Artichokes for autumn bearing. Putting up wall tree protections. Manuring Rose garden beds; also Globe Artichokes. Pruning espalier Apple trees. Cleaning Violet and Asparagus beds.

Feb. 15.—Potting bulbs of Lilium auratum and plunging them in sand outside; also autumn-struck Verbenas and Dielytras for next year's forcing. Pricking off Capsicums. Putting in cuttings of Mangles and Christine Pelargoniums; also some scented Verbenas and Heliotropes. Planting Potatoes under the protection of a south wall. Putting Artemisias out-of-doors. Boxing Ageratums and putting them into Vinery. Putting young Mignonette on sunny side of pits. Examining Rose-tree ties and re-staking them where necessary.

Feb. 16.—Digging in manure amongst Gooseberry trees. Manuring Strawberries. Top-dressing Calceolarias with a good layer of cow manure; also Peach trees, Apricots, Pears, and autumn Raspberries. Putting soil consisting of four parts loam and two leaf-soil into Cucumber pit. Hoeing among young crops.

Feb 17.—Cleaning walks. Slightly increasing atmospheric moisture in Orchid houses. Sowing Parsnips; also Radishes under the protection of a wall and netting them. Potting off Petunias and placing them in Peach house; also Lobelias, Adiantums after division, Gazanias, and Achimenes. Pricking out more Lobelias, Celery, and Cauliflowers, the latter in a two-light box.

Feb 18.—Sowing London White Cos and Malta Drumhead Lettuces; also Champion of England and Veitch's Perfection Peas, Broad Windsor Beans, Spinach, Dutch Forcing and Early Horn Carrots on south border, and Early Dutch Turnips. Shifting Golden Chain Pelargoniums into 6-in. and 8-in. pots, putting three or four plants into a pot, in order to make large plants, and placing them in heat on Vinery shelves. Potting Heliotropes. Filling all spare cases with Cauliflower plants. Planting Jerusalem Artichokes. Preparing a pit for first Melons. Making ready cradles for the protection of tender bedding plants. Starting third Peach house at 55° by night.

Feb. 19.—Potting last autumn-struck Fuchsias into 3-in. pots for early flowering. Potting spare Cucumber plants in case of accident. Shaking out old scarlet Pelargoniums and re-potting them. Manuring orchard. Clipping Ivy on walls.

Glasshouses.

Orchids.—The potting of these should now be pushed forward. As a rule the best time to disturb them is when they are commencing to make new growth; and any plants of Cattleya, Odontoglossum, Miltonia, &c., that are in this state should receive a shift at once. The soil most suitable for the greater number of species is two parts sound fibrous peat and one part Sphagnum Moss, with a liberal addition of charcoal. A soil of this description, in which peat forms the principal part, will be found much more lasting than one composed chiefly of Sphagnum, which quickly decays, except on the surface, and it does not contain sufficient nourishment to produce fine spikes of bloom. In potting Odontoglossums, keep the plants well elevated above the rim of the pot. The advantage of this will be found when the plants require repotting, as the greater part of the roots will be in the cone of soil above the rim, and can be washed clear of the old material without doing them much damage. These generally require repotting oftener than most Orchids, as in every stage of growth a plentiful supply of moisture at the root must be given, which has a tendency to produce speedy decay in the material about their roots. Cattleyas should be potted level with the rim of the pots, and they should have about 2 in. of compost placed under them. When potted in this way the rhizomes are kept from getting twisted in the way they do when the plants are potted on a convex surface, and they can be moved into pots a size larger without disturbing the roots when potted level; by knocking off the rim of the old pot and boring a few holes in the side they can be transferred to a new pot without the slightest check. The shadings should now be put in order, and any not likely to last through the season should be replaced by new material.

Stove Plants.—Where the different soils have been properly aërated, the potting should now be commenced in earnest. Epiphyllums done flowering should receive a slight pruning, which will induce them to break freely. Any plants of Eucharis that have recently bloomed, and which have overstocked their pots with bulbs, should now be shaken out and the bulbs separated. These should be repotted into good-sized pots, placing eight or ten bulbs in each pot, and the pots should be plunged in a moderate bottom-heat, which will materially assist in giving them a good start. Gloxinias, Achimenes, Caladiums, and Gesneras should now be started. As soon as the Gesneras begin to develop their foliage they should be removed to a shelf or pit, where they can be kept free from being syringed overhead, as this quickly disfigures their foliage. One of the most useful spring-flowering stove plants is Glonera jasminiflora. This is now showing its trusses of bloom, and will be assisted with a little clear soot water.

Ferns.—The stronger-growing kinds should now be taken in hand for repotting and propagation if more stock is required. Varieties having creeping rhizomes can now be parted with safety, and a large stock may quickly be worked up. The Gleichenias will require the greatest care in parting them, as it is useless to cut them up in small pieces and expect to establish them. In propagating these the best plan is to place a few pots round an established plant, and on these the rhizomes can be pegged till established. Seedlings make the best plants, but spores are not so free in germinating as those of most kinds of Ferns. Those who desire to raise Gleichenias from spores should sow them on nodules of clay, and not submit the seed-pan to more than an intermediate temperature. I have seen many seedlings of G. Speluncæ, G. hecistophylla, and G. dicarpa raised in this way. The old fronds will now begin to discolour, and must be gradually removed as young ones develop. The temperarure of Ferneries may now be slightly raised, and more moisture maintained in the atmosphere.

Greenhouse Plants.—Autumn-blooming kinds of greenhouse plants, such as Cassia, Witsenia, Habrothamnus, Ophiopogon, &c., should be got into free growth as early in the season as possible. These should now receive liberal shifts, and be placed in the warmest positions in the house. Cytisuses, Coronillas, and Correas going out of flower should now be trimmed into shape, and should receive a thorough cleansing with the syringe. The different varieties of Agave, Yucca, Dracæna, and other fine-foliaged plants should be placed in favourable positions for their development. Aspidistra lurida variegata should now be divided; it is one of the most useful room plants grown, as it stands dust and dry atmosphere better than most plants. Another sowing of Mignonette and other annuals may now be made, including among the lattter Centaurea Cyanus minor, which will yield a large quantity of flowers early in the summer.

Flower Garden.

Pansies and Violas make beautiful beds either in distinct colours or mixed, and in the latter case if seeds are sown at once they will produce good plants for a late display. Both Pansies and Violas delight in a moist, rich deep soil, cow or sheep manure being especially suitable for them, and when liberally supplied with proper food, few plants make a display for so lengthened a period as they do. Carnations, Picotees, Cloves, and Pinks also make beautiful bed or border plants, and Pinks, when well established, make excellent edging plants even without bloom, as their leaves are of a pleasing tint when seen in a mass.

Delphiniums, such as D. formosum, make striking beds and backgrounds for mixed borders, and the Columbines, such as Aquilegia cœrulea, are likewise extremely attractive as well as useful for furnishing cut flowers. The mixed or herbaceous border is a useful addition to any flower garden, providing as it does a home for plants that do not conform to training, and if judiciously planted always contains something that is interesting. Such borders should now be re-arranged, dividing the plants that are getting too large, and filling up vacancies with new varieties. Plant Lilies and Gladioli in any vacant spaces between Rhododendrons, Kalmias, or Azaleas, for, as these shrubs flower early in the season, they are comparatively bare and uninteresting in autumn, unless provision is made to supply floral beauty by means of the bulbs just named. Lilium auratum and similar varieties, and Gladioli of various kinds are quite at home in such positions; in fact, the shelter afforded them in their early stages of growth more than compensates for any overcrowding at the root to which they may be subjected, as they both flourish under similar conditions, and the bulbs will yield a fine display of flowers in autumn, which, when backed by the deep green foliage of the Rhododendrons, well repay the small amount of labour necessary to carry this useful branch of gardening into effect.

Auriculas.—Now that the weather has changed, the surface dressing of these plants should be seen to without delay. It will be necessary to see that the glass is kept clean; mats or other coverings become dirty, and so does the glass. When air is admitted, tilt the lights on the side opposite that from which the wind is blowing; after the plants start into growth they are injuired by cold winds blowing directly upon them. See that all plants that have become dry at the roots during the winter have a thorough soaking of water, and after this they must not be allowed to become very dry. In every collection there will be a number of small plants; these must be repotted when the larger specimens are surface dressed. They ought not to have a large shift; it is much easier to err on the side of over than under potting. The offsets ought also to be removed when the plants are surface dressed. Pot choice sorts singly in very small pots, and the more common varieties six or eight offsets in a 6-in. pot. If the pots are plunged in Cocoa-nut fibre refuse under a close hand-glass, they require but little attention, seldom needing any water.

Carnations and Picotees.—As soon as the weather permits, plants of these not yet in the open ground should be planted. It is a good plan to place 2 in. or 3 in. of good clayey loam over the surface, and when the planting is completed to surface dress with rotten stable manure. Beds that were planted in the autumn should be looked over, and any plants that are loose should be made firm by pressing them into the ground with the fingers.

Gladioli.—As any of the bulbs of choice varieties start into growth, pot each bulb in a 4-in. pot. In our anxiety to obtain the beautiful varieties of G. gandavensis, many of the fine species and varieties that flower in May, June, and July are allowed to fall into comparative neglect. The best plan is to plant out a few

roots of such sorts as G. Colvillei and its varieties, G. cardinalis, &c., in clumps in the herbaceous borders or in the Rhododendron beds along with Lilies, &c., where they can remain permanently, merely protected with leaves or Cocoa-nut fibre refuse in winter. Here they will continue to increase in strength and to throw up a larger number of spikes year after year. Pot the roots now, and plant out about the end of March or in April.

Hollyhocks.—Continue to propagate as previously recommended, until stock enough has been obtained. Plants that have been obtained from cuttings last season should now be potted into larger pots, and this ought to be done before the roots have been too much confined. Look over the old stools in cold frames, and remove dead leaves, give air freely, removing the lights entirely on fine days.

Pansies in Pots.—If the plants that have been wintered in 3-in. pots have not been repotted, see to them at once. The stems are generally very long, and in that case they should be pegged down to the surface of the soil in the pots. We have wintered our entire collection in pots and boxes this year, and when the weather is favourable the plants will be put out into beds in rich well-worked soil.

Polyanthuses.—Surface-dress those in pots in the same way as has been already recommended in the case of Auriculas; those in beds should also have a surface dressing consisting of equal parts cow manure and good loam free from wireworm. Cover the stems up to the point where young roots are being emitted.

Ranunculuses.—If the weather should continue favourable let these be planted out in the beds previously prepared for them. The surface should be level and a trifle higher than the alleys between. In the soil, which should be loose, make a drill exactly 2 in. deep, and plant each small tuber so that the crown is 1½ in. below the surface when the ground is made level. The rows should be 6 in. apart, and the tubers 4 in. or 5 in. asunder in the rows.

Vegetables.

The bare appearance of kitchen gardens and the prospective scarcity of vegetables will be apt to induce some to set about getting in crops before the ground is in a suitable condition to receive them; by doing this, however, nothing will be gained, but probably much lost. Early sowing of general crops should therefore only be attempted under the most favourable conditions as to soil and climate, but meanwhile let every bit of vacant ground be dug, and when dry, point, or roughly rake it over preparatory to drawing drills for seed sowing. With the exception of a few second early Peas, Broad Beans, Carrots, Lettuces, and Radishes, the sowing of all else—no matter how favourable the weather may become—would be best deferred another fortnight; but to relieve the pressure of work at seed sowing time, all transplanting operations may be proceeded with now as opportunity offers and weather permits.

The following are some of the operations which it will be desirable to get off hand forthwith: Remove the mulching from Globe Artichokes, and make good blanks with offsets from the larger stools, after which deeply dig and manure the ground. If new plantations are to be made, deep tilth is indispensable, and the plants should be from 4 ft. to 6 ft. apart, according to the nature of the soil. Jerusalem Artichokes are amenable to much the same treatment, and the sooner they are planted the better. A deep sandy soil gives produce of the highest quality, and to soils of an opposite character coal ashes can scarcely be used too liberally in order to ensure clean tubers of good quality.

Dig and manure ground for Rhubarb, and make good blanks; new plantations should be made by planting single crowns only, and though the produce by the autumn will be usable, none should be pulled the first season, as such a check hinders its full development the following year. The roots that have been lifted for forcing this season, if planted early, make good plantations for open-air produce next year, subject of course to the conditions before named. Make fresh plantations of Seakale, as cuttings can be had from the plants that have been forced, or from seedling plants that were sown last year. For light soils, abundance of farmyard manure is essential to the production of fine crowns, and for soils inclining to clay fresh stable litter is best. The cuttings should be in straight pieces of about 4 in. in length, and of a thickness of not less than 2 in. in circumference, and they should be planted with a dibber rather deep in lines 2 ft. apart and 1 ft. asunder in the row. All the summer culture they will require to obtain forcing crowns for next season will be the removal of any flower-stems that may appear and an occasional deep stirring of the soil. Prepare cuttings of Horseradish, and plant them exactly as directed for Seakale; if extra fine produce be desired, as soon as the crowns are visible mulch the ground all over with farmyard manure, and give plenty of water in dry weather.

Lift all Asparagus roots intended to be forced this season; the remaining plantations should then be very lightly pointed over, in order to break down the winter's mulching, and incorporate it with the soil. A good dressing of salt at this season would prove very beneficial, except where the soil is of a tenacious character; and if applied to all such soils, it should be in dry weather only. Where new plantations are in contemplation, if the ground has not already been prepared, it should be done at once by trenching as deeply as the nature of the soil admits of, and working in an abundant supply of manure in layers between each layer of soil.

Planting should not be done till the plants have pushed through the soil, which, at the earliest, will probably not be till April. When planting, the ground should be formed into shallow ridges, and the lines for the plants should be formed in the hollow, 3 ft. apart and 2 ft. plant from plant; they should be covered to a depth of 4 in., and as growth progresses the ridges should be gradually levelled over the roots. The space between the plants may to some seem unreasonably great, but with the culture here recommended such will not be found to be the case in the second year of growth, and though the practice is not to be commended, the space between the rows may the first season be utilised for a crop of Lettuces or Radishes. In order that the ground may be prepared for other crops, Parsnips should now be dug up and layered in sand in a cool shed. Celery may also be dug up and heeled in thickly at the foot of a north wall, and the ground may be trenched for the main crop of Peas or Potatoes. Plant out August-sown Onions, and fill up gaps in the autumn-planted Cabbage plots. In the forcing department see that supplies are kept up by methodically introducing fresh relays of forcing roots. Sow successional lots of Radishes, and Lettuces, Celery, Cauliflower, Coleworts, and Brussels Sprouts, if not yet sown, should have immediate attention, and any of these ready to prick out should be done before the roots get matted together. Cauliflower plants in pits and hand-lights should have full exposure in mild weather, and forcing pits containing Potatoes, Asparagus, Carrots, Radishes, &c., should be afforded abundance of air whenever the weather is favourable.

TROPÆOLUM SPECIOSUM.

In one of your late numbers someone asked about the Tropæolum speciosum. It is a great wonder that this gem has not been more widely distributed. Several English friends who saw it with me last summer (in Ireland) lamented that it would not do in England, which of course is all rubbish, but I find that many persons have the delusion in their head that it will only flourish in Scotland.

I know of no introduction of recent years which is so valuable. Not only is its flower lovely, but so are also its leaves and its habit of growth. The way in which it throws its lovely graceful garlands over every thing that comes near it endears it to every one who sees it, and I think quite excuses a little gossipping writing about itself and its habits. A lady friend of mine introduced it from Scotland into this neighbourhood about four years ago. Fearing that our damp climate (on which even the slightest frost acts with deadly severity) might prove too much for it, she gave it a large cone of turf mould over the roots, and covered the stems with sacking for the first two winters. Now, however, she considers that it is perfectly hardy. I received two plants early last spring, and although everybody told me they would not do on a south wall, I put both my plants on that aspect, and I am sure I was right. One plant ran up on wire, quite close to the wall, grew about 14 ft. high, bloomed abundantly, and has after the last desperate fortnight (with about 29° of frost) only lost about 4 ft. of its top. It has had coal ashes at its roots and a few sprigs of Bracken woven into the wire round the stem. The other plant was allowed to ramble through a Gloire de Dijon Rose, which Rose threw out long branches more than 3 ft. from the wall, all through which the Tropæolum rambled in the most enchanting way, but it did not bloom at all as freely as the plant clinging to the wall, and it was killed to the ground in a slight frost in November, so that I am convinced a hot south wall is the right place for it, except in a very favourable climate. My neighbour (before referred to) tells me that now with her it grows and increases like a perfect weed, throwing up heaps of young plants all round the stools. She has a plant against the front wall of a greenhouse, and its "runners" have spread all through a Laurel hedge which runs from the greenhouse, draping it all like the wild Convolvulus would do. I intended to try it next year both on an east wall and a north one. I saw it in the north of Ireland, in County Londonderry, on a north wall, and it was doing very well, but that was near the sea and much milder than it is here. It is a good plan to take up and pot in the autumn a lot of the young plants it throws up, keep them through the winter in a cold frame, start them in gentle heat in February, and then put them out where they are to live permanently in April, when they will be about 1 ft. high. My plants seeded freely; the seeds are most beautiful, exactly like lapis lazuli beads, but I hear that they take an immense time (more than a year) to germinate, so it is hardly worth while sowing them, as the plant is propagated so freely by offsets. I wish those readers who have tried them out-doors would tell us their experience of Tropæolum pentaphyllum and tricolorum. I read some time ago an article in *The Garden* in which it was said these two if protected in the winter with a slight covering were sure to do, and flourish and bloom during the summer when so treated with a luxuriance which would surprise those who had only seen them as pot plants. I have got a bulb of pentaphyllum, but my seedsman advised me not to try tricolorum, as he said it would be only throwing money away. Should pentaphyllum be put into gentle heat to start it?

Q. Q.

Double Daisies are among the most popular spring flowers, and in order to grow them successfully they should be treated as follows: In the month of May take the old stock roots up and divide into single crowns, which immediately plant with a dibber, about 6 in. or 8 in. apart, on light, well dug, and manured land, and if the weather is dry one or two good soakings of water may be given them. They soon strike root, when they should be kept well hoed and

Double Daisy (Bellis perennis flore-pleno).

clear of weeds, all straggling blossoms that may appear being pinched off. In September they should be lifted and planted out when they are in flower; if in a sunny situation all the better. In this position during February, March, and April, they will be in perfection, with as much earth as possible adhering to their roots. There is a pretty variegated kind called by some the Aucuba-leaved Daisy, which makes a good edging for a border, and is well worth growing.

Soil for Lilies.—In an answer in GARDENING as to the proper soil for Japan Lilies, *i.e.*, speciosum, auratum, and longiflorum, it is stated that peat or peat and loam are the best. Now, although I quite agree with this for border cultivation, and have after some years of experiments, found it essential that each bulb should be well surrounded with peat and sand, though the soil under that may be richer if the drainage is good, I have not found peat and loam or loam and sand give nearly such good results with potted Lilies as the following: My garden is but a small one and without convenience for rubbish heap, &c., so for the sake of neatness I had a corner about 8 ft. each way walled and fenced off; into this go all sorts — occasional barrows of manure that may be over, sweepings, grass, prunings, &c. I have frequent burnings to prevent too large an accumulation. Each spring all is piled up to one side, and Vegetable Marrows sown on the top, which do well, whilst the other side is taking the accumulating rubbish. In the autumn and winter for potting my Lilies I use the old heap which is then upwards of a year old, passing it through a coarse sieve. There is a good deal of charcoal and charred stuff in it, which keeps it very light and open. Some of my neighbours grow Lilies rather largely, and in peat and loam, but the difference is considerable. My Lilies are altogether finer; both foliage and flowers are larger and brighter. Last year my best pot auratum had on one stem, 7 ft. high, 28 flowers, a grand pyramid; but my largest bulb, a monster given to me as a curiosity by a large firm of Lilium auratum importers, produced only two flowers, but they were Lilies indeed, 15 in. in diameter, of the bright crimson striped variety. This year the bulb is a fine healthy one, but hardly half its original size; this I find is frequently the case with the very large imported bulbs of auratum, whilst the medium and smaller frequently increase in size, as do almost always the imported speciosum and longiflorum, in the soil I use for potting.—W. A., *Broxbourne*.

Nemophilas.—As a plant for the decoration of window boxes or for growing in baskets or pots for greenhouses, or windows, or for culture in the open air, the Nemophila has few equals. A box 6 in. in width will afford a delightful display of bloom. Good-sized pots filled with plants of Nemophila are worthy of a place in the conservatory or verandah; indeed, the uses to which this beautiful hardy annual may be put are so numerous that it would be difficult to say where it would be out of place. The periods of the year at which Nemophila seed should be sown are early in August for spring flowering, and April for summer blooming. If it be possible to sow the seed where the plants are to flower the results will be most satisfactory, but if transplanting be necessary it should be done with great care.

We find in seedsmen's lists about twenty varieties of Nemophila. Although it is probable that between many of these the difference is slight, a selection of seven or eight kinds might, however, be made with advantage. To the insignis class has been added an improved kind known as insignis grandiflora, the flowers of which are large and of a clear bright blue, and a good companion plant to this is found in grandiflora alba, the flowers of which are pure white. In this section two new and distinct hues of colour have been added in the forms called lilacina, the flowers of which are of a pleasing shade of lilac; and purpurea rubra, which has puce-purple flowers, although a new hue in this family of plants. In other sections some striking kinds have been also added, among which may be mentioned auriculata, a kind of crimson brown in colour with a white eye, and vittata, a velvety black margined with white. Another strong-growing section is that of which the type is maculata, a form well known for its large-veined and spotted flowers. The best representatives of it are maculata albida, which has white flowers blotched with purple, and m. grandiflora, white-veined and blotched with purple. There is also a variety in which the foliage is variegated. Among the forms of Nemophila atomaria are some very attractive dwarf compact-growing kinds that are well adapted for small beds or edgings; these are atomaria cœlestis oculata, clear blue blotched with black, and atomaria elegans, the flowers of which are pure white with a dark chocolate centre.

Nemophila maculata albida.

THE COST OF FLOWER GARDENING.

SOME time ago we pointed out the weakness of Mr. David Thomson's argument against the expense of hardy flowers, owing to the cost of the stakes, and instanced many important families in which stakes were not required. The resorts to which he or his aids in his magazine are driven to defend their position may be judged by the following extract referring to our remarks:—

> Any species or varieties, however beautiful their flowers may be, if they require support in the way of stakes, are reluctantly admitted into the hardy collections, and, as a consequence, the greater number of the most beautiful, showy, and useful of our hardy herbaceous plants are not admissible in the ideal flower garden of those who advocate the abandonment of the bedding-out system. Fancy the result of excluding from the herbaceous garden the stately Delphiniums, the beautiful Aster-like flowered Pyrethrums, several species of the Lily family, Carnations, all the taller kinds of Phloxes, and a host of representative members of other families that in this windy island of ours it is absolutely necessary to stake in some way or other, if we would see them in all their beauty, and not as bedraggled, bespattered, betattered objects—highly illustrative of their fitness for admission into the ragged brigade!

The reasoning power or fairness possessed by anyone who invents an untrue and ridiculous statement for the sake of controverting it in his own fashion are not of a high order. Such words are invented for us who have always fought for a place for every beautiful thing (when there was nought but sneers, as well as now, when there is ample promise). But if fair rejoinder will not help them, inventions of the above type will not answer better. They are too late in the field to stop improvement, and will no doubt cheerfully acquiesce in progress as soon as their surprise and indignation are past. This is already clear from statements that each system has its place—the very thing we have always contended for, it being too notorious that many places, and very large ones, had only one phase of garden decoration, and that crude, limited, and geometrical. It is also untrue that we advocated the total abolition of bedding, inasmuch as we have always stated that within due limits and tastefully done it has its place and its charms as well as other plans, but we have never spared the gross blunder of trusting to it only for our main garden decoration.

Hollyhocks from Seed.—For decorative purposes, seedling Hollyhocks from a good collection are almost equal to named kinds, and there is, as a rule, more vigour about seedling plants than about established ones, and they are less liable to fall a prey to that terrible fungoid disease that has done so much injury to Hollyhocks in some districts. If the seeds be sown immediately in a warm house or a hotbed, and the young plants potted off and well attended to afterwards, most of them will flower this year. Hollyhocks are biennials under cultivation in the open air; but by sowing early in the year, and growing them on liberally with heat and plenty of moisture till the end of March, and hardening them off and planting them out in April, they will be converted into annuals. Some of them will probably be later in flowering, and it is possible that one or two may miss flowering, but nearly the whole will flower well, and continue blooming till quite late in the season, most likely till cut off by frost. In order to have fine spikes, the soil should be deep and rich, and should have been well loosened up and manured some time previous to planting. Unless this has been well done, make large holes where each is to be planted, and put in each hole half a bushel of rotten turf and manure in equal parts and plant in it. This will be a good plan to adopt when planting among shrubs, or in any position where it is not convenient to trench the ground.

HOTBEDS AND THEIR USES.

THE heat generated by the fermentation of leaves, stable manure, and other waste vegetable and animal substances is, when under proper control, so genial and stimulating and, withal, so cheap, costing little in most country places beyond the labour of collecting and working up, that it forms the most economical mode of forcing all crops that require only a few weeks or months for their production; and when exhausted, the materials are still available for manure, and when a proper place is assigned for

them there need be no litter or untidiness. February and March are months during which hotbed making begins in earnest, and if a large heap of fermenting materials be ready for use during the spring the production of many crops besides Cucumbers, Melons, and Potatoes may be made more certain and simple. Leaves alone, when in sufficient bulk, will force all kinds of vegetables, but it is always best to mix a proportion of stable manure with them; about half of each is a good proportion. When all the materials are collected together, the manure and leaves should be well shaken up and mixed. If there are dry spots in the heap, these should be watered, as there must be a certain amount of moisture present to insure fermentation. When the heap has lain ten days or a fortnight it should be turned over and well shaken together again, throwing the outsides of the heap into the middle and watering any further dry spots, so that a regular even state of moisture exists throughout. Early Cucumbers or Melons, if grown in hotbeds, will require the most attention and the greatest nicety in the preparation of the materials and the proper bulk of the beds.

Cucumbers started in February should have the beds at least 3 ft. longer and wider than the frames—*i.e.*, they should project beyond the frame 18 in. on all sides. The bed should be 5½ ft. high at the back, and 4 ft. high at the front; this will give it a good pitch to the sun. It should be put together carefully, and of the same substance and firmness throughout, so that the heat may be regular and steady. If made too solid the heat will be slugglish, and if left too open the heat will, perhaps, be too great. There must be a certain amount of air mixed with the material to insure steady fermentation, and if that amount be exceeded or curtailed, the result will not be so good, and it is here that a little practical knowledge becomes useful, as something depends upon the condition of the materials as to the amount of pressure that ought to be applied. Very often a bed may be put up, and will answer admirably without any treading at all, simply beating it down with a fork as it is built up. In other cases this will not make it firm enough, and it has to be trodden moderately firm. In many cases some shelter should be applied to hotbeds. A row of bundles of Pea sticks set up endways on the windward side has a wonderful effect in keeping the heat steady during boisterous weather. Shutters reared up against the bed on the windy side will also answer the same purpose; anything, in short, that will furnish shelter.

Hotbeds for forcing Potatoes, Carrots, French Beans, and other vegetables, will not require so much preparation, and need not be so large as those for Cucumbers, and, if placed in front of and close to the Cucumber and Melon beds, leaving plenty of space between the rows of frames to get between them, they will answer the purpose of linings to the latter, and it will be, in fact, altogether an economical arrangement. I have tried this plan often, and found it very advantageous, as the space between the rows of frames could be filled up almost as high as the top in cold weather. I have occasionally, when I had much forcing to do, had as many as three and four rows of frames all ranged closely together in parallel lines, and the heat in such a bulk of material is always regular and steady, and not nearly so much labour is required. The frames in the centre row would be occupied with Cucumbers and Melons, and the outside rows with Potatoes, Beans, Carrots, &c.

As the season advances, a good deal of forcing can be done with only a limited quantity of material. Digging a hole in a sheltered corner 2 ft. deep, and filling it full of hot litter and leaves, returning 6 in. or 8 in. of the mellowest, driest soil, will make a capital bed for early Radishes, Early Horn Carrots, White Dutch Turnips, or raising young Onions, Leeks, or other plantt for transplanting which may be desired early. Take the case of early Long-pod Beans; if planted thickly on such a bed in a sheltered place, when the weather becomes more settled they can be moved to a more open situation, and nothing transplants better. Any plant that transplants easily—and almost all will do so, if pains be taken with them—may gain a week in point of time by being started on one of these open-air hotbeds without any glass at all. Mats or netting, or even evergreen branches, or a little straw may be used to cover and protect the beds in cold weather.

Cabbages, Lettuces, Cauliflowers, and Brussels Sprouts may be sown early in February on such a bed in small quantities, in order to have a few plants to put out early, or to fill up vacancies caused by the severe winter. In some places there will be a scarcity of green vegetables, and an effort should be made to push forward crops to fill up blanks as early as possible.

Later in the season hotbeds of a temporary character are exceedingly valuable for purposes of propagation, such as the rooting of cuttings or raising seeds. Lobelias, Alternantheras, Iresines, Coleuses, and similar plants may be raised on slight hotbeds in April, dibbled into a thin stratum of light sandy soil on the top of the fermenting materials. An ordinary frame placed on a bed of fermenting materials 3 ft. deep at back and 2 ft. deep at front, say in the middle of April, will hold hundreds of small cuttings. The warmth from such a bed will be just sufficient to root the cuttings and then decline. Healthy cuttings of most plants in such a genial bed will strike in a week, and at that season, if more stock be required, the tops may soon be taken off and dibbled into another bed of similar size, and as soon as the cuttings are fairly rooted, abundance of air can be given, until finally the lights can be removed altogether. Although I have mentioned the middle of April, yet of course everything depends upon the work to be done and the conveniences for doing it; yet I may say that the best and most lasting beds of Lobelias which we had last year were from cuttings inserted in a very slight hotbed the last week in April. To be able to grow these plants in frames in spring without a single pot relieves the houses, and also the labour, a very great deal, and there is no loss as regards efficiency; on the contrary, in that respect there is an improvement.

H.

SPRING FLOWERING BULBS.

Flowering bulbs associate well with all kinds of plants; for room decoration nothing excels them, as they harmonise beautifully with Ferns and other fine-foliaged plants; and a few Hyacinths and Narcissi in the conservatory impart a spring-like appearance thereto, such as is scarcely to be obtained by the use of any other flowering plants. In the arrangement of bouquets the bells of the Hyacinth are invaluable, the shades of blue being very effective. Tulips are not so highly valued as in former times, and by many are stigmatised as gaudy, but the scarlet Van Thol is very acceptable early in the year, being bright and distinct, and I certainly must confess to a large share of admiration for those grand varieties, the yellow Tournesol and Rex Rubrorum. They need the companionship of light, feathery foliage, and never appear to so much advantage as when associated with Maidenhair and other Ferns. They should, indeed, never be so placed that the eye rests upon them in their entirety, as the foliage is not in proportion to the size of the flowers, which renders them somewhat glaring and obtrusive. In Covent Garden Market they are often seen planted with small Ferns and Mosses, and this arrangement is probably the most tasteful that can be adopted. In the open air they have a more natural and pleasing appearance when growing near shrubs; they do not look well massed in beds in open situations—indeed, to my mind, this is not the place for any kind of bulb, their organisation plainly indicating that they need the fostering care of a more robust vegetation. I am not now writing from the florist's point of view, as I am aware that where a choice collection of Tulips is maintained, the grower so manages that his beds are in some way sheltered. I am merely alluding to the planting of the more common kinds with a view to their successful growth, without any special care being needed at blooming time; and this desideratum is best realised by choosing sites naturally congenial to them. As an instance, let us take the Daffodil. Where does it really appear most at home, and flower in the best manner? Not growing out of the bare earth in exposed situations, but springing from the fresh, bright turf, and where the heavy rains and furious winds are broken from them. I know a wood where the Daffodil and Primrose grow in the wildest profusion. Luxuriant masses of foliage spring up through the Grass and Mossy turf, and are covered with thousands of blooms. At flowering time it is indeed a scene of picturesque floral beauty, and is a point of pilgrimage for flower lovers, who carry off cartloads of them. It is very certain that more might be accomplished in this way than has generally been attempted, not on a large scale, perhaps, but there are few places where some portion of the garden could not be dedicated to this purpose. It is not so much the extent as the arrangement which charms, and in this matter we must, as far as possible, follow Nature's teachings. The modest little Snowdrop and the wild Hyacinth are always found peeping out from the midst of Grassy verdure; there would be something incongruous in their appearance if seen growing in the bare earth. Their home is where they are in constant association with other forms of vegetable life, and their near relatives will, I imagine, be found to thrive best when similarly situated.

B. C.

Noble Maiden-hair Fern (Adiantum farleyense).

Adiantum farleyense.—Few plants have attained a more deserved or wider popularity than this beautiful variety of Maiden-hair Fern. Like most other plants, it had to pass through the trying ordeal that most new or rare plants do, viz., being overdone with kindness when first introduced by being grown generally in too high a temperature and in too light a

soil, which, by the way, is a common error in the case of many other Ferns; but since a compost of nearly all turfy loam and sand has been substituted for one formed principally of peat, and the night temperature reduced to that of a warm greenhouse, or to a minimum of 55° in winter and 65° in summer, much finer plants are grown in one year than we used to get in two seasons' growth. At present we have some fair sized specimens of it in 8-in. and 10-in. pots that were only taken off in the form of single crowns with one leaf attached to them last spring, for when robustly grown they form such large fronds that it does not take many to form a large plant. When fully grown they need support, as the weight of the leaf is too great for the leaf-stalk, and for this reason large plants of A. farleyense will never be so generally useful as the smaller-leaved section of the Adiantums; but as specimen plants for exhibition, or for indoor decoration, when large single vase plants are required, there are very few plants that can surpass well-grown specimens of this noble Fern. It is readily increased by division, and being a free and continous grower, large specimens of it may be secured in a limited time. It delights in abundance of moisture at the root, good drainage, and a moderately moist, but not over-exciting atmosphere. Its highest beauty is attained when a large crown of young fronds is thrown well above the older ones just as they have assumed that rich sunny tint so peculiar to the transition state, to the deep green of the fully-matured leaves. A. farleyense is well worthy of a foremost place wherever Ferns are grown or leaf beauty appreciated. We lately saw a quantity of healthy young plants of this Fern in the Fern house in Mr. B. S. Williams' nursery at Upper Holloway.

ANSWERS TO QUERIES.

4137.—**Renovating Camellias.**—It is not one of the easiest matters to bring Camellias that have got into a bad state of health into good condition, and only time and patience can do so. In the first place procure some clean flower-pots of the same dimensions as those containing the plants, some broken crocks for drainage, and some fine peat mould, mixing with it quite one fourth of coarse river sand. Then turn a plant carefully out of the pot, and with a pointed stick work away as much of the old soil as possible. When the roots appear to be at all decayed, cut away the diseased part with a sharp knife, but be careful not to injure in any way such fibres as may appear healthy. It is probable that a considerable amount of the old mould will come away, as it often happens that when unsuitable composts are employed, or if the pots are too large, or watering is carelessly practised, that the roots never enter the fresh mould when the plant is shifted, and the compost, instead of imparting fresh life and substance to the plant proves a source of disease and decay, so that unless removed the roots cannot regain their normal activity. Having proceeded thus far, the next thing to do is to replace the plant in a pot; choose one that will just contain the roots, and, taking care that it is well drained, place first a few pieces of rough mould on the drainage, and fill in round the old ball with the fine soil, tapping the pot down smartly on the bench, but not ramming the compost either with the fingers or with a stick, but pressing the surface quite firm. Before repotting, however, well sponge each leaf, for the health of a Camellia much depends upon the foliage being maintained in a clean state. The middle of March is a good time to perform the work, and the soil should be moist, but not too wet, as it may then be worked away more easily. Be careful also to use the fresh compost in a moist condition, so as to avoid heavy waterings after potting. Place the plants altogether in one part of the house, water gently, shade from hot sun, syringe them in warm weather twice a day, and keep them rather close, but giving air in mild weather. They should not be pruned the first year, as every leaf is of importance. The first season they will not make a strong growth, but they will make good roots, and will go away freely the following spring. We would not repot again next year, but would allow them to get thoroughly established before shifting them on into larger pots.—C. B.

4126.—**Improving a Grass Plot.**—The Grass plot has evidently been neglected. It should be mown as soon as the weather breaks, and well rolled or beaten with a wooden beater. Dress with wood ashes or soot, or a mixture of both. A few Grass seeds may be sown on the bare places, although, if the present turf be encouraged it will no doubt succeed. Guano—3 lb. to the square rod—will be a beneficial application where the turf is thin and poor.—E. H.

4146.—**Plum Tree, how to Manage.**—Have the Plum sucker grafted about the end of March, or as soon as the tree is in the right condition; secure the scions some weeks previously, and lay in moist earth till required. I expect allowing such a strong bantling to grow beside the old tree was the cause of its death.—E. H.

4074.—**Garden on the Clay.**—Coal ashes are a very valuable article in improving stiff, clayey soils, opening the texture and breaking the adhesiveness. They also possess some manurial properties, and the calcareous matter they contain imparts the warming and sweetening quality common to substances that have undergone combustion. Lime rubbish, acting mechanically as an alterative, will also assist in rendering the clay more friable. Mix the substances together, as you suggest, and give a liberal dressing, breaking up the clay as finely as possible, as the more intimately the substances are mixed the greater will be the effects of the application. Should the clay, however, be of a very strong and tenacious character, a much better plan would be to trench your garden (if it is well drained) in autumn, bringing with the underspit a few inches of clay to the surface and leaving it in narrow ridges through the winter to undergo the pulverising effects of frost. When dried by March winds the ridges will level down in a finely comminuted state, and be in the best possible condition to receive the compost, when the whole should be well mixed and incorporated by the fork. If this be now dug in deeply a further mixture will be effected with the bottom spit, a portion of which will be brought again to the surface. Of course you must be guided by your supply of ashes as to the quantity of clay you bring up to be operated on. The quality of the clay would also require consideration, for, if any part of it be of a barren, stony character, it had better remain where Nature has placed it. Coal ashes are said to produce scab on the tubers of Potatoes, but I may say that this assertion is quite at variance with my own experience. It is certain, however, that Rhododendrons exhibit a strong dislike to coal ashes, and other peat-loving plants may possibly possess a similar antipathy. I should consequently consider coal ashes a dangerous ingredient in a compost for general potting purposes. If you cannot procure loam use some of the best of your garden soil with a liberal admixture of drift or river sand, and a little leaf-soil or very rotten manure; and to succulent plants, as the Cactus, Kalosanthes, Mesembryanthemums, &c., an addition of lime rubbish would be an advantage.—J. Martin.

4133.—**Covering Greenhouse Walls.**—If there is a border and pathway between the stage and the wall, and a good depth of turfy peat and loam can be secured, Camellias might do; they would not mind the shade so much if they had justice done them in other respects. The following plants will also thrive: Abutilon Thompsoni, A. Boule de Neige, Fuchsias, Myrtles, Habrothamnus elegans, and Magnolia fuscata. The green fly, of course, must be destroyed by Tobacco fumigation.—E. H.

4139.—**Plants for Shady Garden.**—The best town creeper for balcony or wall is the Virginian Creeper, but of course it is naked in winter. If there was room for the Clematis Jackmani, Cotoneaster, and Virginian Creeper to grow and blend together, the combination would be very pretty, because there would be always something attractive. I should plant the Wistaria and the Evergreen Thorn on the fowls' house. I never heard that Sweet Brier had such a destructive effect upon plants growing near it; but if two plants are growing where there is only room for one, the strong will eventually overgrow the weak.—E. H.

4121.—**Cool House Orchids.**—The following are all excellent kinds and may be grown either on blocks or in baskets: Barkeria Skinneri, Cœlogyne barbata, Oncidium bifolium, Dendrobium chrysotosum, Lælia anceps and autumnalis, Acineta Humboldti, Angræcum falcatum, Sophronitis grandiflora militaris, Cattleya citrina, and Dendrobium formosum gigan-teum. There are, however, many fine species which cannot well be grown on blocks, but which are of easy culture in baskets, and I should certainly recommend the beginner in Orchid culture to adopt this method, as being more easy and more likely to conduce to good results. It may be as well to state that the baskets here referred to are made of deal, are of various sizes, and may be purchased complete and ready for use. Many Orchids commonly grown in pots would succeed much better in baskets especially in the hands of those not well up in the culture of this tribe of plants. The compost should consist of Sphagnum and lumps of fibrous peat in equal proportions, adding to it some crushed charcoal. Some beautiful kinds which may be grown in this manner, and which should be found in every Orchid house, are Odontoglossum Alexandræ, Lycaste Skinneri, Masdevallia coccinea, ignea, and Harryana, Cypripedium caudatum and insigne Cymbidium eburneum, and Epidendrum vitellinum. For all these a minimum temperature of from 40° to 45° will suffice. The great point in the culture of cool Orchids is to maintain at all times around them a moist, equable atmosphere, for they never thrive with any degree of vigour when the air in the structure is inclined to the side of aridity. Thus, in the winter, when, as is often the case in severe weather, brisk fires have to be maintained, the paths should be well damped down, and where the plants come anywhere near the pipes it is well to stand some pans of water, the gradual evaporation from which will tend to neutralise the parching influence of the heating medium. During the summer time every means must be taken to preserve a genial growing temperature, shading in hot weather and creating as much atmospheric moisture as possible. Good Orchid growers like to top dress their plants with living Sphagnum Moss, and by creating atmospheric conditions favourable to it, so that it remains in a green growing state, they know that they are best promoting the welfare of their plants. The atmosphere of a cool Orchid house should indeed be that most favourable to the growth of Ferns and Mosses, and where one class of plants will flourish the other will thrive. Be, however, at all times careful with the syringe, which in the hands of some is really an instrument of torture, A slight dewing in the height of summer may be beneficial, but atmospheric humidity must be created by the means already alluded to.—J. C. B.

4143.—**Covering Back Wall of Greenhouse.**—A Vine or Fig tree might be grown on the back wall of greenhouses; so also might Camellias, if the border was well made, and that must be an essential condition for the former-named plants. There are many things besides Geraniums and Fuchsias that might be grown next summer. A good deal might be done with such annuals as Balsams and Celosias. Harrison's Musk makes a beautiful greenhouse plant for either pot or basket. The tuberous Begonias are very easily managed, and so are Petunias, double and single.—E. H.

4131.—**Nicotiana longiflora.**—Last autumn I bought a 7d. packet of seed of Nicotiana longiflora from Gibbs and Co., and planted same in a box of good garden mould, a little silver sand and peat well mixed together, and kept in a temperature of 60°, the result being 25 nice little plants. When about 3 inches in height I placed them in 2-in. pots, and as they grew, have given two more changes into larger sizes. They are all now in bud and ready to open. I have not lost a single leaf from any, and they now look perfect. My greenhouse is one put up by myself, 25 ft. long, 14 feet wide, pointing north and south, enabling me to have both sun and shade, and able during our severe winters here to maintain a temperature of 50° to 55° at night. It is heated by a double brick flue; fireplace outside, and coals burnt. Winter generally costs about £2 10s. for fire, and I find I have always a flower to show a friend when he calls. Camellias I find hard to flower; all the buds drop off, which is annoying, but I hope by reading Gardening to do better.—W. T. Kilgour.

—— According to our experience of this plant, it is best grown on from seed every year. The seed should be sown either in warmth in March, or in a cold frame in April in light sandy soil. When the plants are large enough to handle, prick them out into 6-in. pots in a free compost, keeping them tolerably moist, shading a little from hot sun, and maintaining the necessary atmospherical conditions by sprinkling overhead in hot weather. The great point is to get the young plants into free growth early in the year, and keep them moving along briskly without check until they come into bloom. When large enough pot them off into small pots and treat as before, shifting the next time into 4½-in. pots, using a compost of two-thirds loam and one-third leaf mould, with a little white sand to keep the soil free and open. During the summer months a cool, well ventilated greenhouse is the best place for them, and if well attended to in the way of watering, they will grow into robust specimens and will flower freely. We have never grown this plant the second year, but those having specimens may do so. In April the old soil should be mostly shaken away and the plant repotted, cramming the roots into a pot just large enough to hold them, and treating the same as recommended for young plants.—J. B.

4132.—**Mice and Crocuses.**—Any kind of mouse trap, especially the well-known figure 4 trap, should be set near the Crocus bulbs. Killing the vermin if possible is the best protection. Some good may be done by dressing the soil about them thickly with soot or with a thick layer of coal ashes, as it is difficu t for the mice to burrow in loose material. Then chopped furze full of prickles may prove deterring, as also may straw chaff. A little paraffin sprinkled into the holes will help to deter them from entering. The best plan, however, is to endeavour to catch them, for having once tasted the Crocuses they are difficult to keep in check.

4140.—**Frozen Potatoes.**—Any Potato that has been hard frozen so that it is softened is absolutely useless for planting and will soon rot altogether. If any seem not absolutely frosted allow them to remain for a week or so and then their value for planting will soon be seen. Planters must be suspicious of all tubers that at planting time have blind eyes. As to your Onions rotting, it is most probable that they were imperfectly ripened last autumn, and are now keeping badly; the complaint is somewhat common. A hot summer is the best to secure good keeping Onions.

4141.—**Frozen Plants.**—We fear there is little hope for your greenhouse plants after the severe freezing to which they have been subjected. The evidence of mischief shown is pretty conclusive that hope is out of the question. A greenhouse imperfectly heated is a treacherous friend, fair enough when times are smooth, but failing at the moment of trial. You may presently cut back what of the plants seem to have life and in a few weeks it will be seen whether they are alive or not. The Fuschias may not be injured, as their wood is harder; you can simply cut all back and wait the result. —A. D.

4119.—**Quick-growing Ivy.**—The broad plain-leaved Irish Ivy is one of the fastest growing and best kinds for your purpose. It will, when well established, make shoots from 3 ft. to 4 ft. in length, and has fine dark green leafage. Plants in pots may be had for about 1s. 6d. each. A good strong-growing Clematis is Jackmani, one of the best of the strong kinds. It should have plenty of root-room. The variegated Japanese Honeysuckle would intermix well with the Ivy, and present in the leafage a striking and pleasing contrast.

4123.—**Slugs and Ferns.**—No doubt not merely one but several dressings of soot would presently get rid of the slug amongst Ferns. A frequent search by candle-light would also be productive of much good, as a great number might then be caught. The soot should be fresh, and be sprinkled after dark, as it would then both deter and kill. Lime would be more objectionable, but when fresh slaked is very destructive to the vermin.

4124.—**Lapageria rosea.**—The Lapageria rosea will if in warmth make growth nearly all the year through, but the spring and summer is its proper growing season. There can be no better time for transplanting than in the spring—say towards the end of April—when the increasing warmth will soon induce fresh roots.

4120.—**Cobæa scandens.**—This plant flowers during the summer, and the blooms are effective. It is best to allow free development, although if a wall has to be covered with it, the points of the young shoots may be nipped out.—C.

4130.—**Liming Garden Walls.**—The lime will not injure the fruit trees by the wall; on the contrary, if they are mossy it will benefit them. The work must be done with care.—E. H.

4136.—**Liming Cropped Ground.**—Do not apply the lime till the crops are off. Then it can be dug in and mixed with the soil at once.—E. H.

4187.—**Worms in Pots.**—I have a Fuchsia in a large pot in which there is a lot of small worms. Will soot thrown around it damage it? and will it have any permanent effect in killing the worms?—W. P. H. [Soot water will do the plant no harm and help to kill the worms, but a good handful of lime put into a gallon of water and well stirred and afterwards allowed to get clear, will if applied to the soil be most beneficial.]

4188.—**Buying Chrysanthemums.**—Is the present a good time to purchase Chrysanthemums for pot culture? and if so, are established plants in pots better than cuttings for flowering next winter?—OSMAN. [The present is a good time to buy either plants or cuttings; plants would give the least trouble, but we do not know that they would give better results than cuttings.]

4189.—**Ridge Cucumbers.**—*A. B. C.*—Sow in pots in a frame in May to have strong plants to put out in the end of June, or sow in the open air in the beginning of June, giving the plants some protection.

4190.—**Bignonia radicans.**—Is the Bignonia radicans really hardy? that is, will it do on a sheltered south wall with slight protection in the winter in rather a cold damp climate.—L. L. L. [Yes].

4191.—**Potting Geraniums and Fuchsias.**—When ought I to shift Geraniums and Fuchsias, and what sized pots should I use?—SUBSCRIBER. [Turn them out of their pots in March, and shake off most of the soil from the roots. Prune back long straggling roots, and repot in clean well drained pots of the same size as those you took them out of, or even smaller ones if the roots will go in them conveniently. Pot into larger pots about the end of May if you ened large specimens.]

4192.—**Sowing Primula Seed.**—*T. W. G.*—Sow in March for early flowering, and in April and May for succession.

4193.—**Book on Orchids.**—The "Orchid Growers' Manual" (B. S. Williams), Burbidge's "Cool Orchids," "Orchids for Amateurs," by Britten & Gower, are good books, and may be had from our office.

4194.—**Vegetable Seeds.**—I have some vegetable seeds the surplus of my last years sowing which have been put away in sealed packets, can they be used with certainty this year?—CONSTANT READER. [Yes; sow rather thickly in case they should not germinate freely.]

QUERIES

4195.—**Sowing Acacia Seeds.**—I have some Acacia seeds. Will some one tell me how I can sow and grow them?—BUTTERFLY.

4196.—**Bird Lime.**—Will some reader of GARDENING give me practical instructions how to make bird-lime? —G. P.

4197.—**Climbers.**—Will some one give me the names of a few handsome greenhouse creepers such as would run over roof (inside) and make a good shade.—W. G. P.

4198.—**Plants not Flowering.**—I have a small forcing pit with the temperature usually between 60° and 70°, which is not very successful; Spiræas, Salvias, Cyclamans, Gesnerias, &c., never flower and any buds which form turn brown; they are well watered at the root. Is it that the atmosphere is too dry? —E. C.

4199.—**Plants for Windows.**—I wish to fit up my windows like the one illustrated in GARDENING, Jan. 29. Will some one kindly inform me what hardy, quick-growing creepers will be suitable for windows with northern and western aspects?—CHUMLA.

4200.—**Water Plants in Greenhouses.**—In GARDENING for Jan. 22nd, an article on "Water Plants in Greenhouses" was given. I should be greatly obliged if anyone could give me a little more information on the subject, especially as the cost of such a tank as described, say 4ft. square and about 18 in. deep. Is it absolutely necessary for the tank to be of slate? Would galvanized zinc or iron do as well, or be injurious to plants? My greenhouse is a lean-to and as it is used for general purposes stove-heat is not attempted, but during the late severe weather we have maintained abont 40° or 42° on the coldest nights. Facing the south-west in a very open situation it has plenty of light and with the exception of pathway is filled with staging. This being the case I had thought of placing a tank under the stage facing the light and should be glad to know what aquatic or semi-aquatic plants would be most likely to thrive under such conditions of temperature and situation. Any suggestions from those having had experience would be most acceptable.—M. W., *Reading*.

4201.—**Growing Tomatoes.**—Will any reader give me full instructions how to grow Tomatoes? My garden is late and cold, and as I have a very sunny greenhouse, I thought it would be better to grow them in it in pots; what sized pots? Also, the kind of soil, manure, &c., do they require? The seed I have is of the Conqueror.—R. G. M.

4202.—**Scale on Peach Trees.**—Will any reader inform me what course to take with Peach trees infested with brown scale in a cold lean-to house? — F. LIONEL

4203.—**Cutting Down Laurels.**—After this severe weather should Laurels, &c., be cut down at once? or not before March or April, the upper part being apparently killed?—CONSTANT READER.

4204.—**Manure for Azaleas and Camellias.**—Is manure requisite for Camellias and Azaleas? if so, what kind? and how much? Also, when will it be best to repot them? They are most of them young plants.— J. B.

4205.—**Stocks for Exhibition.**—What kind of Stocks are the best for supplying cut blooms for show? and how should they be treated to be ready in August? —J. B.

4206.—**Utilising Frames.**—Will any one suggest the best means of utilising wood frames (seven), with lights, and a good boiler attached? I want to keep plants during winter, and grow Melons, Cucumbers, and other things during the summer. I want especially to know the best arrangement for the flue and pipes? Also, where to build the divisions under the frames, so as to use manure for bottom-heat? I have the use of hot water when the manure heat goes off.—Q.

4207.—**Propagating Clematis.**—I have a few plants of spring and autumn-blooming Clematis, but have hitherto failed to propagate young plants from the same. A neighbouring gardener informs me they require budding the same as Roses upon the wild stock. Can any one inform me where to procure wild stocks and how to work them?—T. H.

4208.—**Making and Planting Window Boxes?** —I shall be glad if some reader will give me a hint on making a window box for outside window-sill. What kind of wood is best? Also, what plants will be best to grow in it, especially dwarf climbers? The window, which is a bay, has a south aspect.—G. J. W.

4209.—**Hedychium acuminatum.**—I have a plant of this, and shall be glad to know when it should be repotted, and also what soil and temperature it would thrive in best.—Mrs. T. W.

4210.—**India-rubber Plant in Windows.**—I shall be glad if some reader will give me some hints on the culture of the India-rubber plant (Ficus elastica) in rooms, and also the reason why blotches appear on the leaves, thus causing them to decay.—TOWNSMAN.

4211.—**Heating Greenhouse.**—Owing to the formation of my conservatory I am obliged to have the boiler (a saddle-back) inside, and of course the plants get very dusty, in fact, spoilt. Would it be injurious to the plants if I heated the water by means of gas-jets placed inside the fire box?—ANCHORIA.

4212.—**Whitewashing Garden Walls.**—I have seen brick walls whitewashed so that they had a nice glazed-like appearance. I was told it was done with quick-lime and oil. Will anyone kindly tell me how to proceed.—NORTH SHIELDS.

4213.—**Border for Pansies.**—My garden is surrounded by a wall 11 ft. high, the border at the foot of the wall is 6 ft. in width; would the border with a due north aspect be too shady for show and fancy Pansies? or would an east aspect (with the shade afforded by tall shrubs on the south side of the plot) suit them better? —OSMAN.

4214.—**Frozen Cacti.**—Will anyone tell me how to treat two Cactuses that have been frost-bitten? they are very soft.—A. B. C.

4215.—**Roses in Pots.**—Some time ago I asked advice about Roses in pots; it was kindly answered. I repotted and pruned them and put in a temperature of from 45° to 50° and they soon began to grow. Marechal Niel soon showed bloom-buds from every point. After the bloom-buds had formed I moved it into a temperature of from 55° to 60°, and it seemed to be doing well, until lately I observe the leaves hanging down as if flagging, and now find they are rapidly falling off. What is the cause? It has had plenty of water, and I have given it weak guano-water (a teaspoonful to 2 gals. of water twice only. On one of the late cold nights the fire did not do well and the temperature fell to nearly 40°.— A. B. T.

4216.—**Leaves of Plants Turning Brown.**—I have a small greenhouse heated by pipes and a star independent boiler with good draught, and in which I burn coke. Can any one tell me the reason why the leaves of my plants turn brown and curl up as if burnt with a temperature not exceeding 55°? and what is the remedy?—E. L. L.

4217.—**Pruning Clematis.**—I have three Clematis, Henryi, lanuginosa, and Gipsy Queen; when should they be pruned and how?—A. B.

4218.—**Making a Propagating Frame.**—Will some reader instruct me how to make a propagating frame in my plant stove? The furnace is built in the house of fire bricks well secured, and I propose making the frame over it some 5 ft. square. I can get any amount of heat, but do not know the best means for regulating it for striking cuttings. I thought of building a brick frame of the dimensions above, and filling in with brick rubble, then sand; would this answer?— AMATEUR.

4219.—**Sparmannia africana.**—How is this grown? —SUBSCRIBER.

4220.—**Gloxinias for Winter.**—I am about to buy some bulbs of Gloxinia. Ought I to keep them out of the ground for some months to come? And when ought I to plant them in order to have them in bloom in November next?—H. S. C.

4221.—**Shrubs for Shelter.**—What evergreen shrubs are best suited to form a hedge to cut off the north wind from my flower garden? The soil is clay and fully exposed to the north. I would like the shrubs to be quick growing, so as to form a protection as quickly as possible.—W. G. K.

4222.—**Newly Made Kitchen Garden.**—My kitchen garden was last autumn made out of a lawn, and was bastard trenched, the turf being buried; stable manure was then dug in, and in December it was, with the exception of a small portion on which some cuttings were planted, thrown up into ridges and ashes and dust scattered over; will it require more manure before the sowing season in March? or how should it be treated?— R. J. S.

4223.—**Spiræa not Flowering.**—I have a Spiræa which flowered well two summers ago, but did not flower at all last summer (after being repotted), and now it has put up one flower-stalk without a single leaf. What is the cause of this? and will the crowns break properly and flower in spring?—T. W. Y.

4224.—**Tacsonia Van Volxemi.**—Will six degrees of frost in a cold greenhouse kill the above climber?— C. R.

4225.—**Strawberry Plantations.**—In the autumn British Queen Strawberry plants were planted on a bank facing the east (the soil sandy loam with some clay and stable manure well dug in). Will they require any further treatment before they flower?—R. J. S.

4226.—**Plants for Winter.**—Could any one give me a list of plants which would supply flowers for house decoration in winter, and also plants which might stand in rooms with gas and ordinary heat without injury? We have a stove house, and ditto with drier heat for flowering plants, large Vinery with centre house for plants (not forcing heat in Vinery), cold greenhouse and a conservatory heated by a stove, yet we are absolutely without flowers for the house. I should say we are just getting up our stock of flowers, as the houses have been neglected.—SUBSCRIBER.

4227.—**Hyacinths in Glasses.**—Do the various colours of the glasses exert any influence on the growth of the plant? What are the best colours? BOSTON.

4228.—**Buds Falling off Geraniums.**—What is the cause of buds of Geraniums turning yellow instead of opening?—SUBSCRIBER.

4229.—**Branching Larkspurs.**—I want to sow two beds now containing Tulips with branching Larkspur. I want the Tulips to remain in the ground, the Larkspur to cover over them when they go out of bloom. My soil is rather a cold damp one, but the beds have been made sandy and light for the Tulips. Will the beginning of March be too early to sow the Larkspur? I want if possible to have it up and the plants fairly strong before the Tulip leaves cover the ground too much.—L. L. L.

4230.—**Climbers for Walls.**—At the back of my house are two walls, each facing nearly due south, but one is sunnier than the other (one being shaded by a wall on the west side). I wish to plant a permanent climber against each, but am uncertain what to select. I should much like if I could have say a Tea Rose and Passiflora cœrulea, but know nothing of their treatment, and therefore cannot decide. Would they be likely to flourish? and if so, what Rose would do best? A few suggestions as to planting and treatment will be welcome? also which should be on the sunniest wall, the Rose or the Passion-flower?—G. H. R.

4231.—**Poultry Manure.**—For what crops is this manure best suited? Is it best used fresh or otherwise? Would it be advisable to mix it in with stable manure for a hotbed? Would Cabbage stalks be an advantage in a hotbed?—CONSTANT READER.

4232.—**How to Destroy Worms in Lawns.**—I have read somewhere that paraffin oil mixed with water will kill worms on lawns. Can any reader tell me the quantity of oil to be used to a gallon of water?—W. P. J.

4233.—**Painting Fern Cases.**—I am making a large Fern case, the pan of which will be of well tinned iron. I shall paint the outside two or three coats. Can I paint the inside without injuring the Ferns? or can I coat the tin with something else to prevent corosion, which will not injure the plants?—SUBSCRIBER.

4234.—**Planting Flower Beds.**—I have a large flower bed in the form of a Maltese cross, the most prominent one in my garden. I want to make it effective for the summer. Will some reader give me a few suggestions as to design, &c.? Would German Stocks (various) and Phlox (various) be good taste for the four ends with scarlet Geraniums for the centre?—MAY.

4235.—**Hoya bella.**—Can any one tell me how and when to propagate Hoya bella? and what compost should be used?—Mrs. T. W.

4236.—**Heating Greenhouses.**—We who are in search of the best and most economical apparatus for heating a small greenhouse should feel grateful to "P.," January 1, to kindly tell us if his stove has or has not a chimney, if 4-in. pipes are the best size, if they extend along two sides and one end of the house, how many rows of pipes, and the distance the rows are apart. We should likewise be glad to know if during the recent severe frost the heat in his greenhouse has not fallen below 45°. Slow combustion stoves without chimneys are strongly recommended by their makers, and if a chimney could be dispensed with, it would be desirable. Will any reader who has given this kind of stove a fair trial favour us with his experience in the matter?—NOVICE.

4237.—**Roman Hyacinths.**—What ought to be done with these after blooming?—ENQUIRER.

4238.—**Glazing Without Putty or Paint.**—Will any reader who has tried this system say whether it answers. Is there not a greater amount of heat required to maintain the same temperature than when the glass is fixed in putty?—E. P.

4239.—**Propagating Diosmas.**—I have tried to propagate the scented Diosma from cuttings and failed. Will some one give me the necessary directions?—Mrs. T. W.

4240.—**Floriferous Nasturtiums.**—Which are the most floriferous Nasturtiums which will do well on a north wall?—L. L. L.

4241.—**Dianthus Heddewigi.**—Which is the most desirable variety of this Dianthus or its like for making bright durable beds; and when should it be sown for succeeding Pansies, which will be removed from the beds about the middle of July?—L. L. L.

Planting Potatoes.—The quantity of seed Potatoes needed to plant ½ an acre of ground must depend upon the size of the seed and the width between the rows. From 15 to 18 bushels however will usually plant such an extent well. As to the advisability of planting grass land with potatoes, knowing well the tendency of pasture to breed wireworm, we should prefer some other crop for the first year; but if potatoes are planted, the turf should either be taken off first and be burned before ploughing, or it should be buried deeply. The better plan would be to half trench the ground, turning in the turf 3 in. deep, then upon that 12 in. of soil, and ploughing afterwards for the planting. No doubt some manure, quite a moderate dressing, would improve the crop, as also would some good patent Potato manure or guano.—A. D.

Primulas Failing.—The tendency shown by your Chinese Primulas to damp off at the base of the plants is too often a common feature, especially with plants that are not fully grown when the winter comes. It is most difficult to check, and, once existent, almost impossible to cure. It most probably arises from the employment of soil that is too tight or stiff, whilst the Primula thrives best and roots most freely in a light, sandy, porous soil, through which the water given can percolate freely. The plants that are not yet affected should have all possible air given them and be kept in the full daylight. The surface of the soil may be gently loosened with advantage, and any dead leaves kept gathered off with the affected plants. Gently scrape the stems of any rotten appearances, and remove the soil slightly round the pot, that moisture may not lie close to the stem. As a rule, the Chinese Primula is one of the easiest to cultivate of all our winter greenhouse plants.

SPOTTED PETUNIAS.

SINGLE-FLOWERED Petunias are among the most gay of summer-flowering plants, and their easy culture and freedom from insects, together with their diversity of brilliant blossoms, render them general favourites with those who have ever once grown them well. A bed of mixed seedling Petunias is very attractive when in full bloom, presenting such a number of varying hues of colour. Seedlings are almost certain to make vigorous growth, hence the necessity of planting them in rather poor soil. They are often employed to form dense masses of colour, and beds of particular varieties are employed, the plants being raised from cuttings. In some cases of using Petunias in the flower garden it is well to raise the plants from cuttings; they do not grow so strongly, nor do they seed freely, and thus the energies of the plants are directed to producing flowers instead of foliage. Selected and named varieties, indeed, should always be propagated by cuttings. Seedlings are very easily raised, and it is not worth while to bother with cuttings. If the plants are required to be large and vigorous when planted out, so as to yield flowers at once, sow the seed in pans in August, and put these on a shelf in the cool shady side of a greenhouse covering them with pieces of glass and shading from hot sun. The soil must be kept moderately moist. As soon as the plants are large enough to handle with safety, let them be potted singly into 2½-in. pots, and kept close and shaded in a warm house till they make root, and then shift them into 3-in. pots to winter there. If they are placed on a shelf near the glass in a greenhouse, and kept moderately dry, they will bear a little frost without injury. It is only those, however, who have but little convenience for raising seeds in early spring in warmth that need trouble to raise Petunias at the end of the previous summer and preserve them through the winter. Those who have a warm house or frame at command should sow the seed at the end of February, and pot off when ready, and grow on into nice strong bushy plants. Single Petunias are excellent plants for the decoration of the greenhouse when grown in pots or baskets. If some plants are grown on into 5-in. and 6-in. pots, and pinched back for a time, to form nice pyramid-shaped plants, they soon become covered with flowers, and remain in bloom for a long period. They should be kept well watered, for they speedily suffer if allowed to be become dry at the roots.

SPOTTED PETUNIAS.

Petunias are also well adapted for growing in stone or rustic vases, as they hang down over the sides, and have a charming effect. The soil used for pot-culture should be light and rich, very free, with quite one-third of silver sand added to it. If the soil is at all sour or of a tenacious character the roots will not move, and the plants will become hard and stunted, and if this once takes place it is extremely difficult to bring them into free growth again; in fact, the great secret of success in Petunia culture is to keep the wood growing rapidly without check, either through getting pot-bound, lacking atmospheric moisture, or becoming too dry at the root. The plants must be kept well stopped, as if neglected in this respect, especially during the earlier stages of growth, they will run up lanky, and become eventually naked at bottom; the flowers-buds, too, must be removed as soon as they appear. The object should be to secure a good base of healthy foliage, and therefore stopping the young shoots should form one of the most important points in their culture during the early part of their growth. It is better to repot often than to give large shifts. As soon as there is enough root to hold the soil together when carefully knocked out of the pot, the plant should be at once put into one a size larger. When the pots are well filled with roots, a little manure water may be given occasionally, which will keep the foliage healthy and help the development of the flowers. For window boxes Petunias are well suited, provided they can get a little sun. If put in a shady place they grow, but do not flower. When grown in pots as window plants, it

plants, it is a good plan to cut them back when they are on the wane, and if a little liquid manure be given them they will grow and flower again profusely. The strain of Petunias we now illustrate is that of Messrs. Webb & Sons, of Stourbridge; a very good one, but the tendency to vary is so characteristic of these plants as now intercrossed in gardens that it gives rise to good strains whenever any one takes the trouble to grow them.

ROSES.

ROSES ON LAWNS.

Growers of standard Rose trees often complain that they cannot get them to live. Many reasons can be given why standard Roses die off prematurely, but the main one is that suitable varieties are not got from the nursery. An order is sent to the grower that certain varieties are wanted in the form of tall standards. It is thought that every Rose will grow on a Brier. Why not? Why should not all Roses grow alike? It is not imagined that the Brier, being of a robust nature, requires a robust-growing Rose to be budded upon it. Weak-growing Roses require a dwarf stock. Vigorous ones will grow on a 4-ft. stock, and will live a good many years. In order to get standard Roses to live and flourish, it is necessary, in the first instance, to go to a nursery and pick out one's trees. There may probably be a trifle extra to pay, but plants should be chosen that have grown two seasons after being budded; they should have compact and moderate-sized heads, and care should be taken that the growth has been vigorous and healthy. Look well at the roots, and see that there is plenty of fibres and no large knobs. Reject all having a large knob or clump at the roots; it denotes old age and a plentiful supply of suckers in an incipient state. Examine the stem of the Brier to see that it is clean and free from bruises, which are often caused by the bites of rabbits and sheep during severe weather whilst growing in the hedge rows.

The next point is to know the habit of the Rose budded upon the Brier. Should the variety happen to be a weak grower, no head of any size can ever be formed on it, and its life will be a short one. On the contrary, should its habit be vigorous, with a free-blooming tendency, that Rose tree may live for many years. If tall standards be desired, the only safe plan to prolong their existence for a considerable time is as follows: Dig out a good-sized hole in the lawn (say 3 ft. square and 2 ft. deep), remove all the bad soil and rubbish, and fill up with a rich compost consisting of decayed turf, rotten manure, and ½-in. bones. Let the holes be already prepared; then plant the standards, tread the roots firmly in, and secure the stems to stout stakes with Cocoa-nut bands. Roses of a robust-growing habit will live a great number of years if planted in the way just stated. When a standard Rose tree dies, the cause in most cases arises from a weak Rose having been budded on a tall Brier, and sometimes from its having insufficient nourishment. How is it possible for a weak-growing Brier Rose to live upon a lawn formed of poor soil, on which a few spadefuls of mould have been thrown, and perhaps only one spadeful of manure added? And yet there are many who adopt this style of planting. Rose trees so planted, however, soon begin to show signs of sickness, and small blooms are the result; if they should manage to survive one summer they die the following.

Roses, in order to flourish, especially standards, must have a good soil enriched with manure in order to make them grow and assume a healthy condition. The soil that the Rose prefers is rarely found on a lawn, and it is for this reason that a large pit or hole must be made as before mentioned. Syringing the foliage during the summer evenings, mulching the roots with manure in winter, picking off caterpillars in spring, the application of liquid manure, and other general routine, must be attended to if fine Roses be desired; spring and summer pruning must also be attended to. If the above instructions be followed, Rosarians, however inexperienced, will be successful.

Subjoined is a list of varieties suitable for growing on a lawn; it embraces none of the weak kinds so liable to disease and death; all of them form large-sized heads, and most of them belong to the finest and best of our exhibition varieties, viz.: *Hybrid Perpetuals*—Abel Grand, Baron Hausmann, Baroness Rothschild, Beauty of Waltham, Centifolia rosea, Charles Rouillard, Charles Lawson, Cheshunt Hybrid, Dr. Andry, Duc de Rohan, Duke of Edinburgh, Dupuy Jamain, Edouard Morren, François Michelon, Fisher Holmes, General Jacqueminot, John Hopper, La France, Lord Clyde, Madame Charles Wood, Madame Rivers, Madame Therese Levet, Marie Rady, Marquise de Castellane, Maurice Bernardin, Nardy Frères, Jules Margottin, Paul Neron, Pierre Notting, Princess Louise (Laxton's), Prince Camille de Rohan, Reynolds Hole, Vicomte Vigier, Victor Verdier. *Moss*—Baronne de Wassenaer, Madame Moreau. *Tea*—Madame Falcot, Madame Levet, Madame Berard, Gloire de Dijon, Belle Lyonnaise. *Noisette*—Bouquet d'Or.

H. Taylor.

Pillars in Rose Houses.—We have just been building a large Rose house, and think that it would be improved by having some pillars in the centre for climbing Roses, but we are rather at a loss to know what kind of pillar would look best, and shall be glad of a few hints on the subject. In the house there is a bed running all round the outer part, in which are planted small standards and bushy plants of Roses, while at the back there are climbers to train over the roof. The large bed in the centre of the house is raised, sloping towards the sides, and filled with Roses rather larger than those at the side, and it is in the centre bed that we think some pillars would be an improvement.—E. M. A. S.

THE SHRUBBERY.

Hydrangeas Planted Out.—I would strongly recommend any one who has Hydrangeas too large for pot culture to plant them out after all danger of severe frost is over in rich, deeply cultivated soil. Here the soil is generally stiff and clayey, resting on broken soft stone, and the Hydrangea with us forms a beautiful flowering shrub, which is very effective during the late summer and autumn months. I may remark that many of the plants produce blue flowers, about which much controversy has been held, but which to me appears to be entirely owing to the character of the soil in which they are planted. As the Hydrangeas submit to lifting and replanting as freely as a Dahlia root, I see no reason why any one resident even in the coldest districts might not have a Hydrangea bed by storing the plants in a cellar during winter, and replanting them in April. They would repay that attention equally as well as many of our ordinary bedding plants.—J. G.

Propagating Willows.—I have found the following plan to be most satisfactory in reference to the growth of Willows in rough ground: Cut out a clean notch on the surface with a spade in lock-spit form; then put in the spade in a slanting form about 3 in. and raise the ground a little more than the thickness of the cutting; slip in the cutting on the flat, not on end, and press down the surface raised with the foot, which is all that is required. The selections of Willows for planting in coppices is a matter of some importance. I have found that Willow cuttings from ½ in. to 1 in. thick and about 1 ft. long are the best.—C. M'D.

Planting Holly Hedges.—Hollies succeed best when moved in April or May, and dull weather, if possible, should be chosen for the operation. August and September are also favourable months for transplanting Hollies. The ground intended for the line of hedge should be trenched from 18 in. to 24 in. deep, and from 3 ft. to 4 ft. wide, turning out bad subsoil and stones and replacing them with rich soil or fibry turf well chopped up and intermixed with the original soil in the line of fence. The plants should be from 12 in. to 18 in. high, bushy and well rooted, and planted just clear of one another. Of course smaller plants will succeed equally well and cost less money, but a longer time must elapse before the hedge will be a sufficient fence against cattle, &c. If the weather and soil be dry when planting wash the soil in amongst the fibres with a liberal soaking of water; finish off the planting by adding a thick layer of litter, bracken, or any rough herbage over the roots; this will prove a sure safeguard should a dry summer follow after planting. All the attention that is necessary for two or three years is to keep down weed-growth about the necks of the plants. When the latter have become fairly established, and have made vigorous growth, their sides may be slightly trimmed, encouraging a broad base and narrow, wedge-like top. Holly hedges should not be topped until they have attained the desired height necessary to form a sufficient fence.

VEGETABLES.

CULTURE OF PARSLEY.

There are several varieties, or rather selections, of Parsley in cultivation, each grower having his own Double or Treble Curled to recommend, and doubtless great improvements have been made in its quality and appearance; but of really distinct kinds there are but few. The principal kind now in cultivation is the Dwarf Curled, a handsome variety, which grows close to the ground, and does not readily run to seed. A variety called Fern-leaved is a very handsome kind, and much used for garnishing, and a kind called Giant Curled is very handsome, but for general purposes the Dwarf Curled is perhaps on the whole the best. There are, moreover, the Napoleon or Celery-leaved Parsley and the Hamburgh Parsley. The former is cultivated for its leaf-stalks, which are blanched and used in the same way as Celery, and the latter is grown for the sake of its roots, which are eaten like Parsnips. Neither of these two varieties are, however, of much value, and therefore they are seldom found in gardens. Though the culture of Parsley is very simple, yet to have an abundant supply of it all the year round is often attended with some difficulty, where spare lights are not available for this purpose, and especially in low-lying moist situations. On cold, stiff, retentive soils it frequently dies off. It can be grown successfully in any light, rich ground that has a dry, porous subsoil. To meet a constant demand, three or four successive sowings should be made from February to May. The seed should be sown in very shallow drills, and be very lightly covered. When the young plants are up and large enough to handle they should be thinned to 6 in. distance in the rows. The first sowing or two will furnish leaves through the summer and autumn, and with care and a little management through the winter, but sowings made in May for a supply in winter is preferable. A dry border should be chosen for it, and where there is a south wall a little sown at the foot of it will always be useful in spring. Before severe frosts set in ample provision should be made for thoroughly protecting a portion sufficiently large to furnish a supply of leaves during several weeks' frost. The coverings should only be put on in frosty weather, and in mild open weather the plants should be exposed. The difficulty of having a supply during winter is experienced where there are no spare lights available for protection, and where the soil is of a heavy, retentive nature. Many ways will

Giant Curled Parsley.

occur to an intelligent mind to meet these difficulties. Where the soil is unfavourable a site should be chosen in some sheltered part of the garden, and a bed should be prepared specially for it by putting a quantity of stone and brick rubbish at the bottom, and on this some soil suitable for the purpose. A sowing made on this towards the end of May, if carefully attended to during the summer months in thinning the plants and picking off any luxuriant leaves that may be produced, will furnish a supply during the winter provided it has some protection from frost.

Growing Early Potatoes.—The way I have found to grow early Potatoes satisfactorily is as follows :—In early autumn, before the rainy season sets in, collect a quantity of fine road scrapings, (if a good quantity of horse droppings is with it all the better). Put it under cover, sift it to take out any stones larger than a marble, mix it with equal parts of common fine sand, and a little leaf mould, and mix the whole dry material well together. If the Potatoes are to be grown in pots they should be 12in. or 14 in. in measurement, and quite clean. Place a piece of perforated tin over the hole of the pot, then commence to fill the pots with half-rotten wet leaves, making them firm, until the pots are half full ; then place 1 in. of the well-sifted and mixed dry material ; then place three Potatoes, about the size of a small egg, in a triangle form on the mixture, 2 in. away from the side of the pot, and cover with 2 in. of dry mixture. Give no water, but place them in a cold dry frame. If they are required early, after a few days commence to raise the temperature gently, for it must not exceed 60° at any time. As the young tops appear give light and air—sprinkle with a little water ; as they grow add more of the mixture as before stated until the pots are full. Water as they require it, but that must be done sparingly at all times, especially when the tubers are ripening, or they will be soft and soapy. From beginning to end give all the light and air possible consistent with your heat ; protect from frost, and when cold biting winds occur let it pass through a flannel tacked over where you give air. If the Potatoes are to be planted out in frames commence with the wet half-rotten leaves, tread them firmly, fill up to within 15. in of the glass, then place 1 in. of your material as before described, place your Potatoes on it in rows, 1 ft. apart, and 6 in. from tuber to tuber. In the rows add more mixture as advised for pot culture. Water sparingly, and give light and air as recommended for pot culture. Cover up with mats from frost, ond during sunshine, with plenty of air, the heat may rise a little higher as the season advances. —J. P.

Vegetable Crops between Fruit Trees.—Excellent examples of good culture may be seen in London market gardens, in which Rhubarb and other vegetables are planted beneath the orchard trees, but an orchard proper should, after the trees become established and when the necessity of root-pruning is not likely to occur, be sown down with Grass seed or laid with turf, which can then be annually eaten off and manured by sheep, frequent digging and stirring of the soil amongst fruit trees being often more injurious than beneficial.

A Good Edging for a Kitchen Garden.—Sow in a small bed some Moss-curled Parsley in August, and about April 10 prick it out along the edges of the walk 1 ft. apart, and two rows instead of one. Behind it sow a drill, or, better, sow in boxes Dell's Beet, and plant it out as soon as it is ready. These two common but all-important plants give the vegetable quarters a dressed appearance.—G. B.

Preventing Frozen Pumps.—I see in GARDENING lately the question of how to prevent pumps being frozen during such severe weather as lately experienced is referred to by "J. W. Y.," but I am inclined to think very few would care to go to such trouble when a more simple remedy is at hand. Have any of your readers tried the experiment of suspending the handle of the pump as high as it will go, thus forcing the bucket down into the water? This is a very old practice, and I believe will prove to be a sure preventive of having frozen pumps, especially those fixed in dwellings. —J. P. HITCHINGS.

HARDY ANNUAL HAIRBELLS.

WITH but few exceptions the whole of the numerous family of Hairbells are very handsome, and those of annual duration comprise some of the most showy. To this group belongs the subject of the accompanying illustration.

Campanula macrostyla.—It is rather dwarf in growth, seldom exceeding 1 ft. high, and a good idea of its singular habit may be gleaned from the subjoined woodcut, from which it will be seen that the numerous branches, which are but sparsely clothed with foliage, are arranged in a candelabra-like manner, and which in addition to the large size and pleasing colour of the blossoms, with the beautiful net-like veins of a deeper shade, render it highly attractive. Its specific name macrostyla, or large style, is given on account of an unusually excessive development of that organ, which is club-shape, and rises erect from the centre of the blossom. It is found growing in sandy soil in the vicinity of Lake Isauria, near Mount Taurus, in Asia Minor, whence it was introduced a few years ago. A rich light soil in an exposed and sunny position seems to meet its requirements. It may be sown in the open border, either during the spring months or in September, to stand the winter, so as to obtain flowers early in the season. Besides this handsome kind there are several other species of the

Lorey's Annual Hairbell (Campanula Loreyi)

annual class that are very desirable, and which have long been esteemed as good old-fashioned border flowers. The best of these are—

Lorey's Hairbell (Campanula Loreyi).—An old introduction from Mount Baldi, in North Italy. It grows 9 in. to 1 ft. high, has numerous branches and small, stalkless, shining leaves. Its blossoms are of a blue-violet colour, and are produced in sufficient quantity to render it a pretty border annual ; it is seen to the best advantage when planted in masses. Its variety called alba, with blossoms of silvery-grey, is also very attractive.

Lœffling's Hairbell (C. Lœfflingi).—This is a showy species, dwarf in habit, rarely exceeding 4 in. high, and it produces a profusion of violet-blue blossoms ¾ in. across. It is a capital plant for the summer decoration of rockwork, or for front spaces in ordinary borders. It is found growing naturally in the cornfields throughout Portugal and Spain.

C. attica.—This is another miniature species, about 3 in. high, with reddish-purple flowers, which are produced abundantly throughout the summer. Its white variety is very pretty, and when intermixed with the original kind is strikingly effective.

The Strigose Hairbell (C. strigosa) is a native of Aleppo and other parts of Syria, whence it was introduced a few years since, It grows about 4 in. high, is a profuse flowerer, and lasts long without any abatement in beauty. Its blossoms are 1 in. across, of a dark blue colour, the rather long tube being of a pale yellow shade.

Venus' Looking-glass (Specularia Speculum).—Though this fine old annual cannot be strictly classed with the Campanulas, it is so often ranked with them that an illusion to it under this head is, on this account, admissible. It is, without doubt, one of our showiest annuals, and besides the large-flowered form called grandiflora, both in purple and white, we have the double-flowerd kind, which is said to come true from seed, and a procumbent variety dwarf and compact in habit, and bearing violet-blue flowers.

S. pentagonia.—This is another well-known favourite with larger flowers than the last, but less profusely produced. Its colour is purple, with the centre of a deep blue shade. This and the foregoing are particularly desirable, for, in addition to their showiness, they invariably scatter their own seeds, which come up year after year and give no further trouble ; therefore they are as useful as the perennial kinds.

A Few Words about Violets.—As I have been very fortunate in growing and flowering Violets during the winter, even without the help of a frame, perhaps a few hints to the readers of GARDENING who have not been so successful may be useful. The Neapolitan I find does best for winter flowering. After the flowering season is over, I always make it a rule to dig up the old bed, and after nicely dividing the roots replant them into a fresh piece of ground that has been got ready for them. A half shady border in the kitchen garden is a suitable place for them, and from these plants I look for my winter supply, as I find they flower much better than runners taken during the early summer, which latter, of course, are better for a later spring supply. By planting the bed about 4 ft. wide and setting the plants 9 in. apart, they can be protected by small Fir boughs placed in the ground and made to meet at the top, which answers very well during sharp weather; during the summer a good dressing of rotten leaves is beneficial to them. I have even during this winter been able to pick not a few, but a fair supply of flowers. I hope others who have not been successful with their Violet beds will try the above plan, which will, I am sure, well repay the trouble.—J. WINFIELD.

Sweet Peas.—I am surprised that any one should find that they cannot make Sweet Peas answer by sowing them in pots and turning them out in the open air when well up. Perhaps they have used heat in raising them, or perhaps they have disturbed the roots in turning them out. Of course in many places Sweet Peas will come up well if sown in the open ground, but in many others, town gardens especially, they are very apt to be eaten by slugs, whereas a good potful, 6 in. high, would escape their ravages. The beginning or middle of February is quite time enough to sow them, and they may be placed in the window of any room where there is not much heat. When the unprotected kitchen garden Peas are being staked is the time to plant them out, and care should be given to watering them.—M. A. P.

Scented-leaved Geraniums.—While zonal, bicolor, and tricolor Geraniums are such favourites, it is to be feared that some of the good sorts in other classes are being overlooked. When one comes to making up a bouquet in winter, a few leaves of the sweet-scented sorts work in very agreeably, especially the Rose, Lemon, and Pennyroyal. In addition to the fragrance of the leaves, they are also quite showy when well grown. For instance, Lady Plymouth is a variety of the common Rose Geranium, with the leaves distinctly variegated with white, the contrast in colour being so decided that it could scarcely fail to attract attention. Then there is Apple-scented, Balm-scented, Citron, Nutmeg, Peppermint, Orange, Myrrh, and (perhaps the grandest of all, in appearance at least) the Fern-leaved. This is a splendid plant, with the leaves so finely cut that they appear more like a mass of green silken fringe than veritable leaves. The plant is a strong vigorous grower, but not coarse and straggling, like the old Rose Geranium.

The White Squill (Scilla alba).—This is not now common in cultivation, being ranked with "Dutch bulbs," all of which in these degenerate days of summer bedding are taken up and discarded. If left in the ground, this useful bulb would breed and multiply. Dog's-tooth Violets, the double Primroses (white, yellow, and lilac), would suit the purpose spoken of ; and I would supply "Lover of Flowers" with Scilla alba.—FLORENCE.

TOWN GARDENING.

WINDOW GARDENING.

(Continued from p. 586.)

Plants on Balconies.—In some places there is a light iron or stone balcony outside the windows of the better class of houses; these afford the opportunity for a grand display, and the same remarks apply as to window-sills. It is much preferable even where plants in pots are used to have boxes arranged on the balcony, and plunge the pots in them in some open material, as directed above; it keeps the roots cool, protects them, holds moisture, and does away with the need for so frequent waterings. Many plants suitable for balconies must be grown in pots, such as Pelargoniums, Calla or Arum Lilies, Spiræas, &c., though the majority of plants can be grown turned out into the soil, as above, with good results. Much larger boxes may be used here with good effect; in fact, have them as large, as wide, and deep as possible, so that they can be conveniently attended to. On large balconies. flat roofs, &c., something like permanent borders can be constructed in this way or with a few stout boards, and quite a flower garden on a small scale may thus be had when there is perhaps no other space for any thing of the kind. Often in such an elevated and airy position plants will do far better than in deep well-like courts, where the plants inevitably get drawn and leggy from the light and air being so far above them.

Treatment of Outside Window Plants. — The last week in May is about the most suitable time to fill the boxes with plants. When these get pretty well grown, so as to occupy the soil with roots, and as the weather becomes warm a plentiful supply of water will be needed, especially if the box stands in a sunny window. Do not, as a rule, give water in the daytime, when the sun is shining, though if the plants are flagging, some may be given at any time at the root only, but do not let a spot get on the leaves in sunshine, or it will turn brown wherever it touches. The best time to water all plants in summer is in the evening, when the sun has set; give a good soaking to the soil and roots, and a gentle, but plentiful shower overhead to cleanse the foliage and refresh the plants. In this way the roots are feeding and the plants getting strength from the moist soil all night long, as evaporation is greatly reduced, or ceases altogether during the night, and so the plants are able to bear the ordeal of the hot day that follows. If water is given in the morning it is all evaporated in two or three hours, and the plants receive but little benefit. Water again in the morning if needed and if the day promises to be hot give a good shower overhead early, so that the foliage may be dry before the sun gets strong. Avoid wetting the flowers as much as you can, as it spoils them so. Do not be afraid of giving too much water in hot or dry weather especially, but leave the plants all glistening and dripping; use a syringe, if you have one, in preference to a watering-pot, as it is more effectual and gentler as well. Manure water should be given two or three times a week as the season advances, as the plants, having filled the box and soil with roots, need some extra nourishment. Use this as directed for pot plants, or it may be rather stronger for boxes. Tie the plants to neat stakes if they require it, and do whatever training is needed regularly and carefully. Raffia Grass is far better and neater for tying than anything else. If you have any climbers put the necessary sticks, strings, or wires to them in good time, and keep them carefully tied up as they advance; never allow them to stay too long without attention and get into a tangled mass.

Plants Suitable for Outside Window Gardening.—I append a list of plants suitable for outside windows, balconies, &c., in pots or boxes:—

Amarantus mel. ruber and varieties
Balsams
Calceolarias (shrubby)
*Calla or Arum Lilies
Carnations
Convolvulus major
Creeping Jenny (Moneywort)
Crocuses
Fuchsias, of sorts
Eranthus hyemalis (Winter Aconite)
Narcissus
Geraniums (flowering zonals and gold and silver bicolors only
Golden Feather (Pyrethrum)
House-leek (common, in pots)
Hyacinths
Ivies, especially the Irish and other vars. are fine in winter
Lobelias
Mignonette
Mimulus
Nemophila
*Pelargoniums (show and fancy)
Petunias
*Spiræa japonica and varieties
Stocks (Intermediate or German)
Sedums (Stonecrop) in pots, the best are S. spectabile and S. Sieboldi variegatum
Saxifraga Burseriana and longifolia
Thrift (Armeria) does well in pots on sill
Tulips
Verbenas (venosa and montana are good)
Yuccas (Adam's Needle), fine in winter.

All these will do well in towns, and can only be slightly added to by such things as Heliotropes, dwarf Roses, &c., for country places. Those marked (*) can only be grown in pots. All the others may either be grown in pots and plunged, or planted out in the soil in boxes; the annuals, at least the Mignonette and Convulvulus, are better sown in their places, and not transplanted. Hyacinths, Tulips, &c., may be planted in outside boxes in October or November; put them in 4 in. deep in rich soil, and surround each bulb with dry silver sand to prevent decay; give little or no water during the winter for fear of freezing. When the crowns appear above ground, if the weather is cold and biting, cover them up for a while with a little heap of Cocoa-fibre refuse or leaf-mould, and if it continues ungenial, use an inverted flower-pot to protect them until fine enough for them to escape being nipped, and for the flowers to expand. B. C. R.

Annual Campanula (C. macrostyla).

Ashes for Walks.—Ordinary coal ashes, cinders, &c., make a fairly good firm walk, but to my mind they never look well. Let me describe how I have treated some of my walks, particularly those in the kitchen garden. I got some blue Staffordshire border bricks, 9 in. long, 7 in. deep, and 3½ in. thick, there is a hole in each one about 2 in. from the top about 2 in. into the brick; in each of these I put a short piece of galvanised wire; the guage I cannot give, but about ¼ in. thick; this keeps the whole length together. These bricks being 7 in. deep admit of being put well into the ground, and their size and weight, together with being tied as it were with the wire, makes an everlasting edging. A coat of tar once a year makes them have a new appearance. So much for the border; now for the walk: I intended to asphalte it, and procured some ashes from our railway station for the purpose, but I found that it would be an expensive operation, and abandoned the idea. I had the ashes put on loosely and rolled, but I found the ashes would not set, and I began to think I had created a nuisance. Not so, however, for my walks are always dry and clean, and when any soil or manure gets out of bounds, instead of sticking to the walk in an ordinary way the rake will remove it readily, and my walk is clean and fit for any delicate feet to walk upon immediately, and this after the heaviest rain. I must now tell where these ashes come from. They are taken from the smoke-boxes of the locomotives after clearing the tubes, and they consist of small pieces of the partially-consumed coal which fly off when stoking, through the tubes. I may say it is nearly free from ashes; in fact it is a black cinder, varying in size from a Hazel-nut to a Pea. There are no clinkers or stones, or discoloured pieces as in ordinary ashes, but simply the cinder which absorbs moisture quickly. It is more readily kept in order on the walks than anything else I know of. Weeds will not grow in it, because the seeds have nothing to germinate in. I got these cinders for fetching, so that my walks are not dear. I really forget the cost of the bricks—I think about 6d. per yard.—Cinder Walk.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

February 21.—Making Asparagus land ready for sowing; getting land ready for Seakale planting; potting Gladioli, Chrysanthemums, Stachys lanata, and Calamint, and pricking off young plants of Feverfew and Lobelia; beginning to pot off Salvia fulgens. Putting in cuttings of Justicias, Heliotropes, Coleus, Achyranthes; Bouvardias, Thyrsacanthus rutilans, and scented-leaved Pelargoniums; starting some Achimenes; putting a slight shading over Cinerarias during bright days; salting all Mossy pathways; Clipping Ivy and cutting out dead Laurels; giving a little soot to all Strawberry plants in bloom and that have set their fruit.

Feb. 22.—Putting some Gloire de Dijon Roses against a south wall, plunging the pots, and nailing the shoots to the wall for very early out-door flowers; planting out Cauliflowers between dwarf Peas; beginning to plant Lapstone Kidney Potatoes; finishing planting Globe Artichokes; staking the earliest Peas; covering more Peas with Asparagus tops to keep them from sparrows; taking up all plants of Winter Broccoli that are showing and placing them under protection; putting some new soil and manure to Cherry trees; manuring Strawberry and Asparagus beds; keeping Rose-house from 50° to 55° at night.

Feb. 23.—Sowing Radishes under the protection of a Peach wall; sowing also early Dutch Turnips, and a frame of Early Dutch Forcing Carrots and Radishes along with them; potting plants of Dielytra for forcing, white Pinks for forcing, and Tropæolum canariense; pricking off Capsicums; putting in cuttings of Plumbago, Scarlet Pelargoniums and Willow, the latter to furnish flower sticks; planting some spare hand-glass Cauliflower plants under cases, and a few potted Potatoes under protectors; putting some Musk into heat, and also the last batch of Rhubarb. Taking young plants of Centaurea and Oxalis out of heat and putting them into cold pit.

Feb. 24.—Potting Heliotropes and cuttings of stove plants. Shifting Schizanthuses into larger pots, also Veronica Andersoni variegata. Potting-off spring-struck Alternantheras, Nepeta, and Oxalis. Shaking out and re-potting previous cut-down scented Verbenas. Sowing Rhodanthe and various sorts of Melons; also some Mignonette under the protection of the Orchid-house wall; and a little Chervil, covering the seed with ashes. Planting Potatoes, Shallots, and Garlic; also some Watercress roots in pond. Pricking off some Red and White Celery. Putting in cuttings of Pelargoniums, Iresines, Mesembryanthemums, Crystal Palace Nasturtiums, and Carnations, the last under bell-glasses on a slight bottom-heat in hotbed frame. Top-dressing planted-out Gardenias with leaves. Digging borders for Carnations and Gladioli; also Celery land for Peas, and dressing the Mint bed.

Feb 25.—Potting Ghent Azaleas and plunging them; also Deutzias. Sowing Tree Mignonette in small pots in heat; also sowing Gourds, Beans, Champion of England and Nonpareil Peas, Spinach, Early Dutch Turnip, Incomparable White Celery. Planting Schizostylis coccinea; also Horse-radish in trenches. Pricking off Sweet Basil, Marjoram, and seedling Tomatoes. Putting in cuttings of Purple King Verbena, Anne Boleyn Pink, and more Dahlias; also Monochætum ensiferum, and Thyrsacanthus rutilans. Putting in Chicory to blanch; also another batch of Seakale. Digging vacant borders, preparing land for Cabbages. Arranging and cleaning old Pelargoniums in pits. Putting pots over Seakale, and covering them up with soil for late cutting. Preparing frames on leaf-beds for young spring-sown Lettuce plants.

Feb. 26.—Potting Heaths in peat; also Ferns in loam, sand, peat, and leaf-mould. Potting off rooted Vine eyes, and boxing and potting off Salvias; also Pelargoniums, Petunias, and Mimulus for flowering in pots. Shaking out and re-potting old Fuchsias. Sowing Onions and Parsley. Planting frames with Potatoes. Nailing and arranging creepers on front of house. Clipping Box edgings. Looking over fruit room and removing all decayed fruit. Cleaning Herb beds and Rhubarb plot. Burning up rubbish.

Glasshouses.

Ferns.—A very interesting collection of these can be formed by means of hardy kinds alone. Where these are grown in pots, and have been protected during winter in frames, they will now be fast swelling up their crowns, and should be repotted before their growth is much advanced. The fine crested varieties of Lastrea Filix-mas and the beautiful forms of Athyrium Filix-fœmina are not easily surpassed by the finest exotic kinds. Some of the hardy North American kinds, such as Adiantum pedatum and Onoclea sensibilis, deserve a place in every collection. The delicate varieties of Cystopteris and the beautiful Polypodium cambricum are better for the protection of a frame in winter. The stove and intermediate kinds must now be shaded on sunny days, and a humid atmosphere maintained in the houses containing them. Ventilate cautiously, as cold draughts act very injuriously on the young and tender fronds.

Greenhouse Plants.—Two very valuable soft-wooded plants for flowering at this season are Eupatorium Wendlandi and Salvia gesneræflora. These should now be assisted with weak liquid manure to fully develop their fine heads of bloom. A good batch of the double-flowered Petunias should now be started in gentle heat for early summer decoration. Mimuluses must now be divided and started in frames. The best of these are the varieties of M. cupreus and M. moschatus Harrisoni. Hydrangeas that have formed their trusses of flower must be kept well fed till the blossoms are expanded. Pot off Chrysanthemums, and keep them gently moving in cold frames. A late batch of cuttings of these should now be inserted; they will prove useful for decoration in the autumn. Keep the general stock of hard-wooded plants well ventilated. Young plants in free growth will be benefited by a light shading on sunny days, and they should now be occasionally dewed over with the syringe.

Flower Garden.

Preparations for summer decoration will now need attention.

Pelargoniums wintered thickly in cutting pots or boxes will require increased space; where crowded together until they are planted out they become weakly and drawn up compared with those that are potted off singly, and by stopping the leading shoot as soon as the plants get well rooted the growth of side branches is encouraged, and one good plant managed in this way will be found to be more satisfactory than treble the number indifferently grown or badly rooted. We sometimes dispense with pots, and use as a substitute rough Moss in which a handful of rich soil is tied round the roots. The plants are then set on the floor of a house or pit, and a little light soil is worked in amongst them, and kept moderately warm and moist. Into this they speedily root through the Moss, and may then be transferred to some temporary shelter to be hardened off, finally planting them with the Moss and the ball of roots entire.

Calceolarias that have been kept in cold frames through the winter will also be benefited by more space; the best plan to ensure well-rooted plants is to spread a layer of from 4 in. to 6 in. of soil on a hard foundation of coal ashes, which confine the roots to the soil. If transplanted now about 6 in. apart each way, and the leading shoots are pinched out, they will make good bushy plants by April, when they should be finally planted in the position which they are to occupy; for unless well rooted early in the season, Calceolarias often prove a source of vexation by going off just as they ought to be coming into flower. By following the plan just named, however, and keeping them at all times as hardy and exposed as possible, we find them to be trustworthy free-flowering plants. The sort which we like best is Golden Gem, a dwarf variety with large massive golden-yellow heads of flower that are produced in abundance as long as any flowers are to be found out-of-doors.

Lobelias, Verbenas, Alyssums, Iresines, Petunias, and similar plants will now strike freely in a brisk moist heat, and as soon as they are well rooted they should be moved to lighter and more airy quarters to harden preparatory to transplanting into boxes, pits, or frames. When the latter are available, and the lights can be drawn entirely off them during mild days, the work of hardening plants is reduced to a minimum. In the case of

Sub-tropical Gardening, potting off seedlings of Caster-oil plants, large-leaved Solanums, Cannas, Centaureas, and other fine foliaged plants will now need attention; they must be kept close to the glass to insure dwarf well-furnished growth, and should be shifted into larger-sized pots as they require it, for unless they are fine plants by the 1st of June, there is little chance of their attaining very large proportions before the season is over. All beds intended for this class of plants should be heavily manured and deeply cultivated in winter, and in spring forked over with steel forks; they will then be in good condition for planting. If

Carpet bedding is adopted a large stock of Coleus Verschaffelti and its improved variety must be propagated; also Alternantheras and the golden-leaved Mesembryanthemum cordifolium must be put in at once. Others, such as Echeverias, Kleinias, and Sempervivums, which form such distinct and quaint-looking beds, or which are so largely used for edgings, as in the case of Echeveria glauca, will now need dividing. The majority of this class of plants strike freely from leaves with the growing bud or eye at the base left intact. Echeveria metallica makes a good centre for dwarfer varieties; any plants of it getting too long in the stem may be cut off and inserted as cuttings in light soil and kept moderately dry until rooted. Any of the Sedums that form such pretty carpets under the above-named class of plants may be pulled to pieces and dibbled in thickly in light dry soil on a sloping bank or border, in order to ensure a good supply by planting time, and the same treatment will ensure a good stock of that invaluable green carpet plant Mentha gibraltarica. All dried-off roots of Cannas, Dahlias, Salvias, Gladioli, &c., should be at once removed from their winter quarters and planted or started in gentle heat according to the supply required. Seedling plants should be pricked off as soon as they are large enough to ensure a dwarf steady top growth and a corresponding mass of healthy fibrous roots.

Auriculas.—All our plants have now been surface-dressed. We found it the most convenient plan to carry the plants into the potting shed, where they were thoroughly cleaned, the surface soil removed, and the fresh compost placed on the surface, pressing it down firmly with the fingers. The pots, which had become very dirty during the winter, were washed, and a sharp outlook was kept for green fly. All the plants were replaced in cold frames, where they will remain until a pit can be prepared for them.

Pansies in Beds.—Plants established before winter must be attended to now. Surface-dress the beds with rotten manure mixed with a little loam. Peg all straggling growths down to the surface.

Fruit.

Plums and Cherries.—Few subjects make a better return for the exercise of patience through the early stages than Plums and Cherries when grown under glass, a maximum of air at all times, when it is not freezing, with a minimum of fire-heat, being the most important points in their management. Indeed, so easily are they excited into the most beautiful sheets of bloom, that it is a matter of surprise they are not more generally cultivated for their flowers alone. By the time these instructions appear many of the early kinds will have unfolded their blossoms, when, like all other stone fruits under artificial treatment, they will require careful fertilisation, with a constant supply of air, the atmospheric moisture being regulated by external conditions. It is important that the house should be liberally supplied with fresh air, with just sufficient fire to keep it in motion, and as night comes on the temperature may sink to about 45° when the weather is cold, and 50° when mild, but in the event of a return to sharp frost the flowers will be quite safe at 40°, with the ventilation considerably reduced and a corresponding reduction in the supply of moisture. For culture under glass the best dessert kinds only should be planted or potted.

Vegetables.

Main crops of Onions, Leeks, Parsnips, Carrots, general crops of Peas, and Broad Beans are the more important crops that should be got in as early as conditions are favourable. The frost and latterly the rain having done their worst, there should now be a general clearance of all crippled vegetation, or at least of such of it as is not likely to recover. As soon as the digging of all vacant plots is finished let each be marked for cropping, and if seeds cannot be then sown the ground may perhaps be in good order for planting out Cabbage, autumn-sown Onions, Lettuces, early Potatoes, and Cauliflowers. The latter require rich well-drained ground and to be planted in deep drills, as they are thereby partially sheltered from cutting easterly winds, generally so prevalent in March, and from the effects of which a little protection should be also afforded to Peas by earthing up and staking them on the windward side with evergreen boughs as soon as they emerge from the soil. As a rule, Peas are sown much too thickly in the row, and the rows are too close together. If the seed can be depended on, 3 in. asunder is sufficiently thick. As to distance row from row, that must depend on the average height which the kinds of Peas grown attain, but plenty of space should always be afforded, and a crop of Radishes or Spinach may be grown in the central space between each row.

Potatoes should be planted in but limited quantities yet, and only in positions where they have natural protection, or where protection can be expeditiously applied, but all the seed tubers should be laid out in single file either on floors or tables in cool sheds or rooms, that the sprouts may be developed sturdily. A little dry Cocoa-fibre refuse scattered amongst them conduces to root formation. Thin out Carrots, prick out Lettuces, Celery, Cauliflower, Brussels Sprouts, and Coleworts, and make successional sowings of all these in the open air, but on a bed of leaves and litter to afford a little bottom-heat; in such a position a first sowing of Broccoli, Cottager's Kale, and Savoys should also now be made. Rhubarb will now come away freely by simply covering over the crowns with pots and just sufficient leaves or litter to keep the frost out of the ground. The crowns of Seakale in the open ground intended to be forced should at once be covered thickly with finely-sifted coal ashes, and the only attention required will be to occasionally examine them to refill the crevices in the ashes which are sometimes made through the quick growth of the Kale. French Beans will now bear most abundantly if sown in pits, but bottom heat, say 60°, is essential, and a top heat ranging from 65° to 70° with plenty of humidity. It is also time to make a sowing for outdoor culture of Tomatoes and Capsicums in order that the plants may be strong for planting out early in May.

GARDEN ENEMIES.

GREEN FLY, ROSE APHIS, OR ROSE BLIGHT.

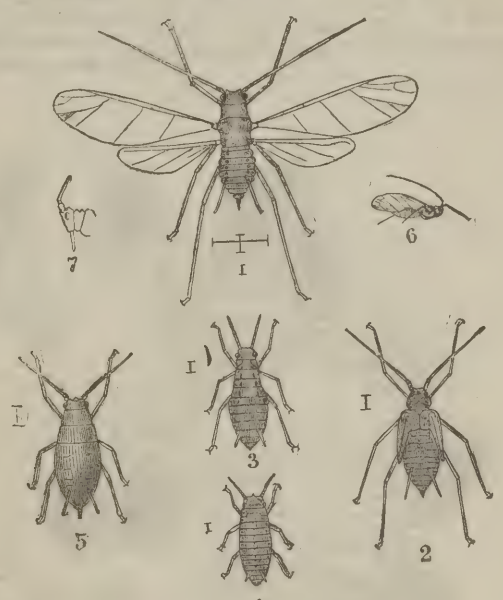
(SIPHONOPHORA ROSÆ.)

This insect is one of the large and destructive family called aphides, which is only too well known to all who have given the slightest attention to the cultivation of plants. It may be classed without hesitation among the gardener's worst enemies, as there are few plants which do not suffer more or less from the attacks of some members of this family. The Rose aphis is unfortunately one of our commonest species, and the injuries which Roses sustain from it are well known to every lover of these flowers. Few Roses are exempt from their attacks, but the Tea-scented kinds and those whose leaves are somewhat evergreen suffer less than others.

These insects are often called blight, and many persons assert that when during northerly or easterly winds in dry weather there is a haziness in the atmosphere, that haze is blight, and caused by immense multitudes of these insects, and urge, as a proof of their theory, the very sudden appearance at times of myriads of these aphides. These insects have not, however, anything to do with atmospheric effects. No doubt they often make their unwelcome presence known in large numbers, and plants may be found covered with them which only a few days before were apparently free from them; but this, no doubt, is due to many of the eggs hatching at the same time, and to the very rapid manner in which their reproduction is effected.

One of the peculiarities of this group of insects is that some of the females never lay eggs, but always produce their young alive, whilst others lay eggs and never reproduce in any other way. The young, which are born alive, begin to produce young in the course of from four to eight days, so that the rate at which they multiply is very astonishing.

The Rose aphis does not entirely confine its attacks to Roses, but infests Dahlias, Asters, Verbenas, and many other plants cultivated under glass. The injuries it occasions to plants when in large numbers is very great, as it deprives the young and tender parts of so much sap, causing the leaves to crumple up and preventing the buds from flowering properly. Numberless plans have been tried for their destruction, but in seasons favourable to their growth it is almost impossible to keep Roses grown out-of-doors free from them. Those grown under glass, however, can easily be kept clean by fumigating them with Tobacco smoke. This plan cannot, however, be so easily carried out with Roses growing in beds out-of-doors; still, by covering the head of the plant with some kind of air-tight cloth, well tied round the stem, the green fly may effectually be killed with the assistance of a fumigator. The cloth should be stretched over a frame, which anyone could make, to keep the buds and young shoots from being injured. Carefully brushing such parts of the plants as are infested with spirits of wine, benzine, or 1 wineglassful of paraffin to 4 gallons of water, kept well mixed, is very effective, as it kills the flies at once. Simply brushing the insects off the plants does a great deal of good, as many are killed by the operation, and the others, once knocked off, cannot well return (except the winged ones). Crushing the aphides on the trees with one's finger and thumb is a very effective, but unpleasant method of destroying them. Syringing with Tobacco water, or a weak solution of sulphate of copper (1 oz. to 6 gallons of water), or an infusion of Quassia chips (4 oz. of chips should be boiled for ten minutes in a gallon of soft water, and 4 oz. of soft soap should be added as it cools); or 2 lb. of washing soda, 1 oz. of bitter aloes dissolved in hot water, when cold add 1 gallon of water; or 8 lb. of soft soap dissolved in 12 gallons of rain water, added to 1 gallon of Tobacco water; or water in which Tomato leaves have been macerated, are recipes which are much recommended; even cold water when applied with some force is very effective. Very rapid changes of temperature seems to check the multiplication of aphides. A heavy thunderstorm will often kill thousands, and cold rain is very destructive to them. The eggs, which are laid in the autumn, do not hatch until the following spring, when all the aphides which are hatched are wingless females. These in a few days begin to produce young, which are born alive, and very much resemble their mother in general appearance, but their legs and antennæ are much shorter in proportion (see fig. 4). After some changes of skin they assume the form shown in fig. 3, and after further moultings, either show the rudiments of wings, as in fig. 2, or else are in an intermediate state between figs. 3 and 5. When in either of these stages, this insect may be said to be in the pupa state. Changing their skins again, they appear as perfect insects, those with the rudimentary wings as alate, or winged females, as represented in fig. 1; those without as apterous or wingless females, as shown in fig. 5. The winged females assist greatly in the increase of their species, for, being able to fly, they can easily move from one part of a bush to another, or fly off to other plants, founding fresh colonies wherever they may settle. They are not so abundant as the wingless ones, except in the spring and autumn, when they frequently migrate in great numbers. About the middle of September the last generation is usually produced, which consists of males and females. The former are sometimes winged, sometimes wingless; they are very much like the females, but are somewhat smaller. The females are mostly wingless and viviparous. After pairing with the males, they lay their eggs, which are very large in proportion to the size of the insect (nearly half the size of its body), a few together near the buds. They are long and oval, and when first laid pale yellow, but soon afterwards become black. They are covered with a slimy coating, with which the female attaches them to the plant.



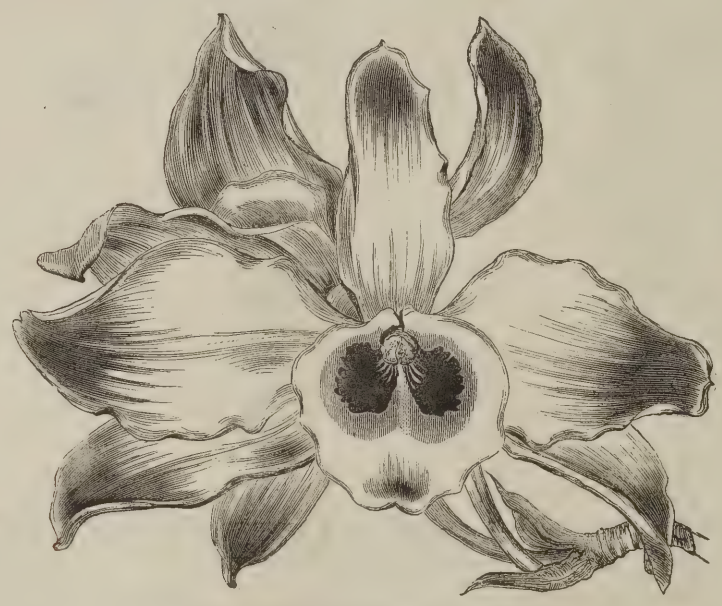
1, Winged female; 2, pupa; 3, larva; 4, ditto just born; 5, wingless female; 6, side view of winged female showing the position of the wings, at rest; 7, profile of head showing the proboscis.

Gas Lime for Walks.—Having lately read in Gardening Illustrated the uses of gas-lime in the garden, I thought it might be interesting to some readers to know that it is a good weed destroyer, preferable to salt in my opinion for gravel walks. I use 2 bushels for 100 square yards, which kills all the weeds and moss, and gives a bright appearance to the walks.—G. W.

ORCHIDS.

Dendrobiums.—The genus Dendrobium is one of the most beautiful and the richest in species in the group of Orchids to which it belongs, the most attractive of which are distributed throughout the different Presidencies of the Indian Empire, and especially in Moulmein, Assam, and Burmah; while others are found in Ceylon and Manilla. As a rule, the Indian species are epiphytal, in their native habitats growing upon trees, both living and dead, and both in sun and shade, the result being that those grown in the sun make shorter and plumper pseudo-bulbs (stems) than those which exist in more moist and shady positions, and, as a rule, the flowers, if not so large, are more brilliant. Two or three species are found in China and Japan, but the most beautiful are Indian, and consequently require a warm and humid atmosphere (that of an ordinary well-managed plant stove) when making their growth, with copious supplies of water at the same time, and a dry, airy, and sunny position when at rest. Some of the finest specimens of D. Wardianum, D. Devonianum, D. crassinode, and D. Bensoniæ perhaps ever seen were grown on in a warm humid plant-stove, to which air was cautiously admitted during mild nights as well as during the daytime; when their growth had attained full size they were removed to a warm and sunny Vinery to ripen. As a rule, Dendrobes may be readily propagated either by layering the old pseudo-bulbs (stems) or by cutting them into lengths and inserting them as cuttings or by dividing strong plants or taking off the side-growths which appear pretty freely on the half-ripened pseudo-bulbs of the previous year. In growing these plants over-potting must be carefully guarded against, for if the roots be embedded in a mass of sour compost they speedily rot, and the energies of the plants are then diverted to the formation of new roots instead of to growth and bloom. Many of the species grow best in small pans, or hanging baskets suspended near the light, and the pendulous-habited kinds look more at home thus managed than when potted and staked in an upright and unnatural position. A compost consisting of fresh fibrous peat, living Sphagnum Moss, and well-dried horse manure suits most of the varieties, coarse, well-washed river sand being added to keep the whole porous; and a well-drained bottom is highly essential, for although these plants will luxuriate

if deluged with tepid water two or three times a day during the hottest summer weather, yet the slightest stagnation or sourness is detrimental to their welfare. The secret of success, indeed, in growing all epiphytes consists in using small pots or baskets of fresh open compost, made firm, so that it does not shift about every time the plant is dipped or watered, and then giving copious supplies of tepid water at the root. It is impossible to over-water plants thus circumstanced, inasmuch as the small well-drained body of compost only holds moisture sufficient to keep the plants in health, and all that is superfluous passes freely away. The culture of many of the most beautiful of all Dendrobes need not by any means be confined to Orchid houses, properly so called; indeed, a few well-grown plants of D. Wardianum, D. crassinode, D. Devonianum, and D nobile look far more beautiful when associated with Palms, fresh green Fern fronds, and other fresh-foliaged plants than when crowded together among other Orchids, scarcely any of which are interesting to an ordinary observer, except when they are laden with flowers. D. Wardianum, which we now figure, flowers as freely as the old and ever-beautiful D. nobile, and quite small plants of it, grown in an ordinary plant-stove suspended from the roof, will produce from twenty to thirty flowers of the size of those represented in our sketch. The colour of the flowers is pure glistening white, each broad segment being tipped with the purest magenta; the ivory-like lip has a golden disk, on which are two dark velvety crimson spots, and there is a pale magenta blotch at its apex. As the plant is now reasonable in price in all good nurseries, it well deserves culture at the hands of all who have a demand for rare and beautiful blossoms during the early spring months. A few flowers of such a lovely Orchid amongst a basketful of white Lilac, Paper-white Narcissus, Deutzia, double Plum blossom, and graceful sprays of Spiræa or Fern will enhance their beauty tenfold.



Ward's Dendrobe (Dendrobium Wardianum).

Utilising Dead Tree Fern Trunks.—The sketch from which the annexed woodcut was prepared was taken in one of the Ferneries at Messrs. Veitch & Son's nursery, Chelsea. It represents Lomaria attenuata growing on a dead Tree Fern trunk, which is clothed also with innumerable seedlings of various other Ferns, such as Nephrodium molle, Polypodium Billardieri, Lomaria blechnoides, &c. This is a desirable method of growing Ferns, as they look more graceful and natural than when cultivated in pots, and they do not require so much attention, as the roots insinuate themselves into the soft, but solid texture of the Fern stems where they are kept at an equable state as regards moisture if water be occasionally applied. Under this treatment some kinds of Ferns thrive better then when grown otherwise, whilst others do not succeed so well. The kinds that thrive best are the Lomarias, Nephrolepis, Davallias, Doodias, most of the Polypodiums, many Spleenworts and Maiden-hairs, &c. A highly attractive feature, too, is the wing of the large tropical Fernery at Kew, where there are admirable examples of this style of growing Ferns, thriving in native luxuriance, mingled with the various kinds of Tradescantia, Saxifraga sarmentosa, &c., and all the attendance they receive is occasional watering and a daily syringing.

ANSWERS TO QUERIES.

4147. — **Hyacinths Coming into Bloom.**—It is not a matter of absolute necessity that the water in which Hyacinths are growing should be changed, but if it smells bad it had best be poured away and other put in its place. It is the rule to put into the water when bulbs are put in the glasses a small lump of charcoal. This acts as a purifier of the water, absorbing noxious gases. Where this is done, and the water keeps pure, there can be no benefit resulting by changing it. Good fresh soft water should be used in all cases, and if thought desirable to change it, the fresh water should be just slightly warmed before coming into contact with the roots. Hyacinths grown in glasses are of little use the second year, but they may be laid in the open ground after blooming till ripe, and stored for border planting another year.—A. D.

4135.—**White Primula in Windows.**—We presume that the double white Primula is referred to, a plant not very suitable for a continued residence in a warm room. We fear that the plant in question will give but poor results. It should not have been disturbed in the autumn; spring is the proper time for propagating it, when cuttings are taken, but it requires good accommodation and an experienced propagator to succeed with them. The only way to treat the double Primula so as to get a fair amount of success when grown in the dwelling is to keep it in an apartment where fires are only occasionally lighted. April is a good time for repotting, but plants cut up in the autumn would not need repotting. Let them remain untouched throughout the summer, giving plenty of air in fine weather. Loam, leaf-mould, and peat in equal proportions forms a good compost.—J. C.

4137.—**Flag Iris Flowering Imperfectly.**—It is very difficult to say what is the cause of the blooms not expanding. There may be a want of general vigour in the plants which might be set right by means of a top-dressing of manure. The Flag Iris likes a well drained, but moist soil, so that in planting them care should be taken to provide a free root-run in congenial soil, and the roots should be able to run down deep in search of moisture in hot weather. When the weather is hot and parching these Iris are benefited by delugings of water, and they like occasional applications of liquid manure.—J. C.

4138.—**How to make Pelargoniums Flower.**—If the Pelargoniums are of the large flowering or show kinds, pot them at once into 6-in. pots, using a soil consisting of two parts loam and one part leaf-mould and sand; "stop" them, *i.e.*, pinch out the points of the shoots once. If, however, they are zonal Pelargoniums, pot them in the same soil in March, and stop them frequently in order to make them bushy; cease stopping them when you want them to flower. In either case keep them near the glass and watersparingly for some time. Temperature, 40° to 45° at night, and 50° by day, with plenty of air.—C. Fielder.

4128.—**Paris Daisy Etoile d'Or.**—We can only assign one cause for this plant not flowering in the winter, and that is want of light. This variety of Chrysanthemum frutescens expands its blooms freely all through the winter in a low temperature, and is really one of the most valuable flowering plants that an amateur can grow. The plants that have bloomed all through the summer may be made to do duty in winter, and will if at all fairly treated yield an abundance of their pretty primrose-coloured flowers which for cutting are extremely useful. The true way, however, to grow this plant is to strike some cuttings in April, grow them along freely through the summer, but in the full sun, getting them well established in 4½-in. pots by the latter end of August. The general treatment will consist in stopping so as to form a neat, compact plant, watering freely in hot weather and picking out the flower-buds until the latter end of August. When the pots get full of roots administer a little liquid manure, or top-dress with some concentrated manure. In this manner good plants will be formed capable of carrying a large amount of bloom; winter them if possible in a light intermediate house where an average temperature of 50° is maintained, or place them as near the glass as possible in a frost-proof structure. If shifted in March they will form grand subjects for decoration in early spring.—J. C.

4141.—**Frozen Plants.**—Your Geraniums are probably all killed. If, however, you are not satisfied on this point you might place them aside for a week or so, at the end of which time you will readily distinguish any which are likely to survive. You can do nothing to save them now. The fate of your Fuchsias may not be quite so lamentable, through being hardier and less succulent than the Geraniums. Keep them dry until they begin to break into fresh growth, then shake the old soil from them, and re-pot with two-thirds loam and one-third leaf soil, rotten manure, and sand.—C. Fielder.

4125.—**Thrips on Plants.**—Having had considerable experience in the use of insecticides, I am quite satisfied that nicotine soap surpasses any other; I use it in the proportion of 3 oz. to 1 gal. water, warm, and have always found the black thrips thoroughly exterminated in one syringing. It also leaves the plants quite clean and glossy in appearance. I am speaking more particularly of Azaleas, Myrtles, &c. For Vines I have recommended it to my neighbours, who in all cases have used it with successful results. I should recommend it in all instances for Vines at the strength of 6 oz. to 8 oz. to 1 gal. of warm water.—H. Hart, *Brighton*.

4162.—**Hotbed for Raising Seeds**—For a frame of the size given the bed should be 8 ft. square, and for the purpose named it should be about 3 ft. 6 in. high at the back, and about 2 ft. 6 in. high or a little more at the front. Mix the old and the fresh manure together; if the former is not much decayed, about equal parts of each may be employed; well shake and mix together and leave it for a week or so, then turn over and shake well together again, turning the outside of the heap into the middle; when nicely sweetened, make up the bed, and place on the frame, and as soon as the drops of condensed moisture inside are clear the seeds may be placed inside.—E. H.

4186.—**Earwigs.**—The earwigs can easily be trapped and destroyed. Pieces of Reed, Bean stalk or Elder with the pith bored out 8 in. or 9 in. long should be placed amongst the creepers on the wall or wherever the insects

abide. The places where the traps are placed should be noted, as the insects will creep into the crevices, and once or twice a day some person should go round with a vessel of hot water, into which they should be flung by blowing down the tube. Roses and Dahlias may be secured from their depredations by placing small empty inverted flower-pots on the top of the stakes with a little hay inside to form a hiding-place for the insects. Perseverance will soon thin their numbers.—H.

4162.—**How to make a Hot-bed.**—Hot-beds should be made early in February. The quantity of manure required depends upon the size of the frame or box to be used. For ordinary requirements the heap of manure when finished should stand 16 in. outside of the frame or box all round. Care should be taken to let the edge of the frame rest well into the heap of horse-manure. When pig manure is used, an equal quantity of horse manure should be used. Pig manure is best for hot-beds when obtained from animals fattening—that from those which have been grazing on commons and roadsides is full of indigested seeds of weed, and should not be used until these have been destroyed by frequently turning over the manure-heap.—BILL-O'-THE-WISP.

4166.—**Guano-water** when applied once a week to Strawberries in a liquid state (4 oz. to a gallon of water) makes them very vigorous and productive; but if sprinkled upon seedlings of the same fruit it would kill them. 2 oz. per yard (5 cwt. per acre) if sprinkled over Onions would double the weight of crop. Ten gallons of water will readily dissolve, or keep suspended in a state of minute division, about 50 lb. weight of guano. When applied to plants not more than 4 oz. should be added to that quantity of water. If it is made stronger it injures or kills the plant to which it is applied. To seeds it should be much more diluted.—BILL-O'-THE-WISP.

4156.—**Vegetables in Shaded Places.**—It was once observed by a great philosopher that he was a benefactor to mankind who caused two blades of Grass to grow where one only flourished before, and I think I might venture to add, or who would prove to us and "F. C." the possibility of growing vegetables under the shade of trees. I would advise "F. C." to allow the ground around the Apple trees to remain undisturbed; their roots extend in every direction as far or farther than their branches, and the deep digging or trenching necessary to the attempt to raise anything would, by disturbing and destroying the roots near the surface, inevitably tend to injure the trees. A few Gooseberries or Currants, black especially, would be found to combine the maximum of profit with a minimum of injury. The only vegetables likely to do any good at all would be Rhubarb, Sea-kale, or early Radishes; that is to say, things that would be likely to reach maturity before the trees got into full leaf, or perhaps Jerusalem Artichokes later on. Some portion of the ground might perhaps be utilised for seedlings of winter greens to be transplanted to some more favoured spot later on, or if the space is a great consideration, it might form the site for a Mushroom bed, or even a hotbed for Cucumber frame, though I would not recommend it.—J. V. A.

4131.—**Nicotiana longiflora.**—I sowed a packet of seed of this on July 19, 1880, in a pot of sandy soil, and covered it with a pane of glass, and placed it on a shelf in a Vinery. From the 7d. packet of seed I have eighty-one nice plants. I potted them first into 3-in. and then into 5-in. pots, using leaf-mould, loam, and common yellow pottery sand (almost any kind of sand will do). They have been kept in a heat of from 40° to 45° in a Vinery, and at the present time are looking very well. They gave me a lot of bloom, which was delightfully fragrant, especially at night. They are now beginning to bloom again. I may say that they suffer a little from the attacks of the green fly, but this is cured by fumigating.—H. SOWTER.

4160.—**Lettuce in Town Gardens.**—I expect "F. C.," who is evidently an observant gardener, has made the mistake of planting the Lettuce under Apple trees. It is very difficult, I might almost say impossible, to succeed in growing a good Lettuce in an ordinary London garden. I was discussing this point with an old gardener one day, and he summed the difference in growth of vegetables between London and the country in a very pointed way. "D'yer see this, sir?" said he, catching up an old Cabbage stalk; "stick this in the ground in the country and you'll have nice young stuff off it; plant it in London, it will rot." To give every chance, sow in the autumn, transplant in the spring into rich soil, at least 9 in. or 12 in. apart, keep them well watered, and select the most open spot in the garden, where they will obtain every available ray of sunshine, and after you have done all this, you will find three-fourths "bolt," and the rest to be without hearts. I would earnestly advise "F. C." not to waste time in the futile effort to raise Lettuces that can be obtained in the greatest perfection quite six months in the year for a half-penny or a penny a-piece. I have written nothing of the difficulty in the early stages of getting enough growth daily to supply the wants of sparrows and slugs.—J. V. A.

4155.—**Substitute for Pea-sticks.**—In my description of this apparatus, figured in

Best way of utilizing Dead Stumps of Tree Ferns.

GARDENING of January 22 (p. 557), the words standard and support are used synonymously. The illustration shows merely one standard, and as it would appear when viewed from the end of a row, the Peas of course being between G and B. Band is a provincial word, signifying cord or string. Let "F. C." in imagination so place himself as to obtain a side view of the standard in the illustration, bearing in mind that it is an end standard. At a distance of 2 ft. 6 in. from the bottom bar a peg not less than 18 in. in length is driven into the ground; a guy rope or straining cord is then fastened to this peg and secured to the top bar of the standard. This being done to each end standard or support, prevents their being pulled out of the perpendicular by the shrinking or contracting of the tarred band when saturated by rain. I can, from an experience of two summers' use, assure "F. C." that the band does contract very considerably by wet, and that it these straining cords are not adopted the whole row of supports will acquire a leaning position more or less, and consequently an unsightly appearance, and ultimately the whole structure will be very likely to collapse. The band slackens by drying, and when this is the case (if the slackening be very considerable) the guy ropes can be tightened, or a turn of the strands can be given round the nails so as to make them taut. Suppose "F. C." has a garden bed 24 yards across, and he purposes sowing a row of Dr. McLean's Pea and using my standards, he would not sow the full 24 yards, but would allow a space of 2 ft. 6 in. from the foot of each end standard and on the outside for the straining cord and peg, so that his row of Peas would in actual length be 22 yards 1 ft. For this length nine standards placed 8 ft. 4 in. or so apart (an inch or two either way is not material) would be quite ample. For tall growing knds, standards of an approximate height would be required, and in addition guy ropes would be necessary on each side of every standard, in order to withstand strong side winds. The standards for tall sorts, such as Ne Plus Ultra, &c., ought not to be placed more than 7 ft. apart, as the weight of the haulm is something extraordinary.—EBORACENSIS.

4171.—**Plant-stand for Rooms.**—In reply to "Alpha," I think the following particulars will give him all he wishes: Mine stands 3 ft. 8 in. high, 3 ft. long, and 1 ft. 6 in. wide; the box or stand being 5 in. deep and 20 in. from floor, 11 in. of glass, castors being 2 in., brings the stand itself to 3 ft. 2 in., the rise of the roof being 6 in.; total height, 3 ft. 8 in. I bought 4 uprights, 3 ft. long by 1½ in. square for legs, turned up 20 in. from bottom; 1 tie-bar, 3 ft. by 1½ in. square, turned up, leaving 2½ in. at ends for morticing into 2 tie-bars (each 1 ft. 6 in. by 1½ in. square), these left square at the ends for morticing into the uprights, and square in the centre to receive the longitudinal tie-bar. I then got 5 in. by ½ in. pine for forming box; these are let into uprights 20 in. from the bottom (using red lead and putty mixed to make these joints, as glue would not do, on account of the dampness in the soil, &c.). Previous to jointing run a slot from the top of uprights down the insides to ½ in. below the 5

by ½ in. for box; this is to receive the glass when finished. Then nail a lath inside the case on the 5-in. board all round to receive the bottom of box. After putting this together put some wooden pegs into the mortice-joints from the inside of the box; mind you don't let them come through to the outside, or it will make it unsightly. You now fit a strip round the top of the uprights (this is to hold the top or roof of the case) 1½ in. by ½ in. strong. The bottom part is now ready for fitting glass. To make the roof I used 1 in. by ½ in. pitch pine laths, putting four sides together (3 ft. by 1 ft. 6 in.), then 4 pieces (to form the tip of roof) 2 ft. by 5 in. (this is for the open space allowed for ventilation). I then get 4 pieces for corners, and, giving the roof 6 in. rise, should be 11 in. long. They must be rabbeted on each side to receive the glass. You now have the roof (hip style) ready for the moulding. Get 8 ft. 1½ in. deep, and about ¾ in. strong on the top edge; nail this on the roof portion to sit on the stand, and let it lie over the lath (already nailed on uprights) about ¾ in. This will hold the top part in its place, will hide the division between top and bottom, and will answer for holding the glass on the top, and being loose you can lift the top on and off at leisure. You must now get some zinc fret-work to place round the space on the top for ventilation. Get a zinc tray made the size of the box, and 2½ in. deep. You now want it glazing, staining, and varnishing. I used oak stain, one coat, and oak varnish, two coats. The timber (best pitch pine) you can get for about 4s. cut to dimensions 8 ft. 1½ in. by ¾ in. Pitch pine mould (choice) 1s.; turning legs and tie bars, 7 pieces, 2s. 8d.; red lead for joints, stain, and oak varnish, 2s. 4d.; fret-work, 2s. for 6 ft. (I was cheated in this; it should only be 2d. per ft.); 4 rollers or castors (brass), 2s. 6d.; zinc tray for bottom (extra strong) 6s.; best glass, cutting and fitting same, 7s. 9d.; total, 28s. 3d. I may say I have never seen or heard of one of this sort before; of course, if you get it made for you it will cost double the amount.—A NOVICE.

4177.—**Repairing Boilers.**—Get some blacksmith to make you a small pair of clamps, and cover hole with sal-ammoniac and iron filings; then screw up.—WIGAN.

4158.—**Potatoes.**—The largest tubers upon a root of Potato are invariably the worst diseased. The reason is obvious. As the fungus spores travel down the plant stems they are naturally attracted into the strongest sap currents, and these would of course flow into the largest tubers. Further, the largest tubers are proportionately to the smaller ones always the most watery. Deep or shallow planting has little to do with it. We prefer to plant shallow about 4 in. deep, and giving plenty of room between the rows to earth up well. Strong growing Potatoes should have ample space, not less than 3 ft. between the rows. Do you mean by "germs of Potatoes" the top growth or haulm? That they are seen short in market gardens is no doubt due to the fact that the sorts have naturally short tops, such as the Ashleaf Kidney, Early Shaw, and similar early kinds. In the open fields where the late sorts are grown the tops are strong enough. The sorts of Potatoes you name, Victoria and Champion, always have very robust haulm growth; the latter especially is excessively so, and fearfully exhausts the soil, whilst the root crop is not at all commensurate. Magnum Bonum is better than this, although it also has a strong top, but the root crop is invariably good. Neither of these coarse kinds should have raw manures given, nor should the soil be too rich. Deeply tilled, plenty of room, and a moderate dressing of some good artificial manure produces by far the best results, both in crop and quality of tuber. It is not wise to plant too many early Potatoes unless grown for sale. Late kinds crop and keep better, and as a rule are of better quality. The Early Rose is useful for first crops, but there are plenty of better kinds.—A. D.

4160.—**Lettuce.**—When Lettuces or any other vegetable run to seed prematurely it is a sign that a check of some kind has been given. The check may not necessarily be from want of water, it may arise from poverty in the soil, or from standing on it too thickly, and the thinning too long neglected, or in some cases it may arise from inherited debility. The remedy is to sow good seeds thinly on well prepared land. Keep the surface freely stirred and mulch between the plants when hot weather sets in with short manure.—E. H.

4161.—**Onions.**—To obtain Onions like the Spanish Onions the land must be dry and rich, both near the surface and below. It must be made firm before the seeds are sown, either by treading or rolling, but this work must be done when the surface is dry, so that the earth will not cling. The seed should be sown in drills 1 ft. apart and the seeds not covered more than ½ in. deep. The young plants should be thinned when large enough to pull, taking away the small ones, leaving them finally 6 in. apart. In the early stages the soil between the rows should be often stirred, but just before the plants cover the ground mulch between the rows with some mellow compost to keep in the moisture. Soot may be used freely as a top dressing.—E. H.

4178.—**Hyacinths and Tulips for Exhibition.**—If the bulbs are now well rooted, and the crowns starting as they should be, although not yet forced, they might now be put into a gentle warmth, that should begin at 45° and increase to 55° as the plants grow. It is difficult to fix the best time to a day, but if pushing too fast, it is easy to retard them by reducing the temperature a little, and so pushing or checking at will.

4179.—**Propagating Tree Carnations.**—As the Tree Carnation is valuable as a winter blooming plant, it is no sacrifice to top the plants now. There should be plenty of time for them to break and make fresh blooming growth before the autumn. Take off the tops somewhat short, and thus leave as many leaves on the plant as possible to encourage breaking.

4181.—**Plants for Windows in Summer.**—A few scarlet and pink Pelargoniums, Fuchsias, Blue Lobelias, single Petunias in colours, climbing Tropæolums, Ivy-leaved Geraniums, Mignonette, Canary Creeper, Abutilons, and a few similar cheap and easy-growing plants will make window boxes look very gay, indeed, all the summer. The boxes may be filled with these plants about the middle of May. Hardy plants may make a nice show for a month or two, but not longer.—A. D.

4104.—**Salt as a Fertiliser.**—Salt must be used very cautiously in the neighbourhood of fruit trees or bushes. I should not advise more than six pounds to be used on the space named, and this quantity should be equally distributed. Fresh lime is a good insecticide, so also is soot, and these substances may be used liberally with beneficial results.—E. H.

4105.—**Propagating Mulberry Trees.**—Mulberry trees are commonly propagated from layers, although they may be rooted from cuttings, though not with the same certainty. Your correspondent had better take a few little plants; any nurseryman could supply him. If he decides to take cuttings the ends could be stuck in a ball of moist clay, and the tops be packed in dry material such as hay.—E. H.

4108.—**Planting Mistletoe.**—Plant the seeds of Mistletoe about the time the sap rises to nourish them, viz., in March.—E. H.

4093.—**Covering Hot-water Pipes.**—Box the pipes up with boards as you suggest; it will be quite safe. Fill the space up with sawdust or some other non-conducting material.—E. H.

4136.—**Liming Cropped Ground.**—You will do well to leave your liming till you have removed your crops. Then dig as soon as possible, and well mix the lime with the soil, or you can spread it on the surface at the time of planting.—W. K.

4170.—**To make Boots and Shoes Waterproof.**—Melt over a gentle fire and stir together till thoroughly mixed 1 pint of neatsfoot oil, ¼ lb. of mutton suet, 6 oz. of bees-wax, and 4 oz. of rosin (resin). Brush the dirt off the boots or shoes and let them be perfectly dry, then rub in the above composition by the fire upon the upper leather, and also upon the soles until they are completely saturated, repeating this operation occasionally.—BILL-O'-THE-WISP.

4148.—**Heating by Gas.**—If "Beckenham" can depend upon a constant supply of gas at a fairly uniform pressure, he can safely adopt it for heating his boiler, but the boiler must be outside the house. I am just discarding gas, as I find in frosty weather the supply cannot be depended upon, owing to water in the mains, &c.—H. F.

4144.—**Primulas Failing.**—If "Subscriber" will turn his Primulas out, it is quite possible he will find the drainage imperfect, which if remedied and care is taken not to water overhead, he will soon perceive the softening of the leaves checked, which is called "fogging."—W. K.

4098.—**Books on Botany.**—I think "Brook's Popular Botany" will suit Miss V. It is a weekly book, price 2d., containing a coloured plate of flowers and numerous wood engravings each week.—PIMLICO.

4125.—**Cure for Thrips.**—There is no better solution for the destruction of thrips than one made of 2 oz. of Gishurst Compound well stirred into a gallon of soft water. It may be used as a wash or syringed on to the plants somewhat gently. This compound may be purchased from any seedsman in 1s. boxes. The soap you name will do the Vines no harm, but double the quantity of the Gishurst put into water and well worked on the Vine rods will be more efficacious. In applying it the dormant eye buds should be avoided.

4128.—**Paris Daises not Flowering.**—It is most likely that the house in which your Paris Daisies are growing has too damp an atmosphere, or that the absence of sufficient solar light causes the flower-buds to die off. It is easy enough to create warmth, but the absence of solar light cannot be remedied. No doubt as soon as the sun's power becomes greater you will get plenty of flowers.

3879.—**Pruning Rosa rugosa.**—This Rose does not like to be hard pruned; cut away all weakly growths and cut back the strong shoots to about two-thirds of their length. We do not know where the white variety is to be procured, but possibly of some of our leading Rose growers.—J. C.

4073.—**Garden Paths.**—I find that sifted coal ashes are very good for garden paths, though not good looking in colour. Weeds are easily kept under and the paths are always pleasant and smooth to walk on.—H. S.

4070.—**Worms in Pots.**—Pour strong soap water round the plant, and the worms will come to the top.—CLYDESIDE.

4184.—**Potatoes for Seed.**—Your Potatoes will do very well for seed this spring, but should be well exposed to light and air to have them thoroughly matured; the growth that will follow will soon absorb the excess of moisture. It may be, however, that grown under similar conditions the produce will be also watery. In such soil it is bad policy to manure too heavily. We found the long fresh stable manure buried beneath the sets in the furrows to give a drier, cleaner, and far heavier crop than where the manure was dug into the soil, as is customary. Give the soil a heavy dressing of hot slaked lime just before planting.—A. D.

4166.—**Guano Water.**—If the guano is to be applied to plants in pots we would advise a small quantity to be mixed with the soil when the plants are potted; it will be then far more completely utilised than when made into liquid manure. Except for plants that have an abundance of roots, manure water should be used very sparingly; seeds hardly need it at all if the soil be fairly good, but as the plants grow it may be applied somewhat weakly,

4183.—**Liquid Manure.**—The drainage from a pigsty will do for plants in pots, but must be well diluted in dry weather. When there is rain no doubt the runnings from the sty would be diluted sufficiently. Animal manures make a rank liquid, and need to be used with care. It is better to apply it too weak than too strong.

4163.—**Celery for Stewing and Soups.**—There is no better flavoured Celery than Major Clarke's solid red. If bulk is wanted in combination with good keeping qualities for late use, then plant Sutton's Sulham Prize Pink. For an early white take the Sandringham Dwarf White.

4187.—**Petroleum Cask for Liquid Manure.**—If the petroleum cask is well painted both inside and out, it will make an excellent receptacle for liquid manure, and the water from such a cask will have no injurious effects upon plants. I have had two in use for years.—E. H.

4186.—**Destroying Earwigs.**—The way I destroy earwigs in my garden in the spring is to place each night a number of clean cloths or dusters on the flower borders, and the old earwigs with a great quantity of young get into the folds, and I shake them out early in the morning. I am then not much troubled with earwigs during summer.—J. J. C.

4159.—**Turnip Beet.**—The Turnip-rooted Beet is an excellent variety. Sow the first for early use about the first or second week in April, and the main crop in the first week in May. The land should not be freshly manured, unless the manure is buried deeply. Draw the drills about 15 in. apart and thin out the plants to 9 in. in the rows. Have the soil well pulverised, but do not cover the seeds too deeply.—E.

4145.—**Glazing without Putty.**—Refer back to GARDENING Nos. 58 and 61, and you will find my account of glazing without putty, and with which I am still very well satisfied.—H. S. H.

4182.—**Cleansing a Paraffin Cask.**—This is best done by burning it out. Stand the cask up on end, the head being out, and throw in a good handful of lighted straw or shavings; the whole inside will soon be on fire. Let it burn well for a few minutes till the inner surface is thoroughly charred. Put the fire out by turning the cash upside down or by throwing a wet sack over. These casks are much used for water butts and washing tubs. For the latter purpose the head is left in, hard-wood plugs are driven into the tap and vent holes, a chalk line is drawn round the middle and an extra hoop nailed on about 1½ in. each side the line. The cask is then sawn across and the two tubs burnt out.—G. J.

—— Stand the cask, bottom upwards, on four bricks, put some shavings under the cask, and set them on fire. When the cask is well burnt and hot, pull the bricks away; this will put the fire out. Have some pitch ready boiling, then pitch the cask all over. 12 or 14 lb. of pitch will be enough for a 100 gallon cask.—W. YEOMAN.

4098.—**Botanical Books for Children.**—The best book, in my opinion, for teaching botany to children is a little work by Professor Bentley on botany. It is one of the manuals of elementary science, published by the Society for Promoting Christian Knowledge, and can be obtained at any bookseller's.—C. B.

4242.—**Manure for Azaleas, &c.**—*T. W. Y.*—Both the kinds of artificial manure you mention are good for the purpose you name; of the two the latter is probably the best, the other being more suitable for field crops.

4243.—**Garden Marigold.**—where can I get seed of the common garden Marigold? No one seems to grow it now, and the kind I mean is not advertised in seed catalogues.—M. J. L. [We presume you mean the common pot Marigold, which may be had from any good seedsman.]

4244.—**Leaves for Hotbed.**—How should they be treated? Should they be kept dry or put out to rot? [Shake them up into a heap of the form you wish the hotbed to be, and well tread them down. If you can mix a little long stable manure with them, you will get a better heat in the bed.]

4245.—**Last Year's Seeds.**—*A. B. C.*—Yes; they will no doubt grow very well. Sow thickly in case they do not germinate freely, and sow early in case of failure.

4246.—**Verbenas from Seed.**—Will Verbenas raised from seed sowed in March flower in summer?—AGATHA. [Yes.]

4247.—*Amateur, Co. Down.*—Kindly ask your question according to our rule, viz., write each query on a separate piece of paper, and write on one side only. We shall then be happy to attend to them, but we cannot answer a dozen questions all mixed up together.

4248.—**Brewing.**—*G. W.*—You can brew beer for your own use without a license.

4249.—**Daisies.**—*D. S. B.*—You probably mean the variegated double Daisy. Any good nurseryman will supply you. It has often been advertised in our columns.

4250.—**Striking Cuttings.**—Is this a good time to strike cuttings of Pelargoniums, Heliotrope, and Carnations for summer blooming?—HELIOTROPE. [Yes, if you have a warm house or frame, and if with a little bottom heat all the better.]

4251.—**Annuals for Windows.**—I wish to sow some annuals—Nemophila, Dianthus, and such like—in pots for a window facing the south. When should they be sown? Would they be best raised in a greenhouse and placed in the window when fairly started, or raised entirely in the window? Occasionally a fire is lighted in the room.—J. J. [Sow now. It will be best to raise them in the window.]

4252.—**Celeriac.**—*C. M. M.*—Sow in April, in rich soil, in a pan or box, in a frame or under a hand-light. Prick off when large enough, and finally plant out 12 in. to 18 in. apart in well-manured soil. When nearly full grown, draw a little earth over the bulbs to keep them white and tender. We have given several articles on the subject.

4253.—**Paraffin Oil on Seeds.**—Will paraffin oil applied to small garden seeds before sowing injure them in any way? I believe it is used as a preventive against mice and birds for Peas and Beans. I have used red lead, but it is objectionable.—H. [It will not hurt them in the least.]

4254.—**Nemophilas, &c., in Pots.**—*Caxton.*—See article on the subject in this week's paper. Silenes may be grown in the same way. Tropæolum Lobbianum will succeed planted in a window box or large pot. Plant in May or June.

4255.—**Tacsonias in Greenhouse.**—I have a young plant of Tacsonia in my greenhouse growing rapidly, but it has only two shoots. Should I cut off the tops to make it spread?—C. H. [Yes.]

4256.—**Flower-pots.**—In a cast of 90's, 48's, and 32's pots are there 90, 48, and 32 respectively?—X. D. [Yes.]

4257.—**Old Seeds.**—I bought seeds from a good house last year, and did not use them all (Balsam, Primula, Marigolds, Dianthus, Œnothera, &c.). Are they to be trusted for this year?—X. D. [Yes; sow rather thicker than usual, and sow early in case of failure.]

4258.—**Telephone Pea.**—*Leho.*—This is a large and excellent Pea. It is a tall-growing variety.

Heliotrope.—Mr. Barr, 12, King Street, Covent Garden, W.C.

Small Scarlet Passion Flower.—*Erin.*—To which do you refer?

Bouvardias.—*Lover of Flowers.*—See article on the subject in last week's GARDENING.

Insects in Potting Soil.—*Subscriber.*—We would not use the soil till the insects have been destroyed. Put some soot with the soil and turn it frequently.

Fly on Crocuses, &c.—*F. L. S.*—Fumigate them with tobacco smoke, or wash them with soap and tobacco water.

Carnations and Picotees.—We can only refer you to our advertisement columns.

G. H. A.—Wait till April or May and then report progress.

Perforated Flower-pots.—*P.*—Mr. Matthews, The Potteries, Weston-super-Mare, or any maker of flower-pots.

Bladiola.—*T. S. M.*—We do not know what plant you refer to.

Subscriber, Guernsey.—The name of your plant is Hoya carnosa. What do you wish to know about it.

Growing Figs.—*Enquirer.*—If you refer to GARDENING, Jan. 15 of this year, you will find a complete article on the subject.

Names of Plants.—*T. S., Isle of Man.*—1, Pteris cretica albo lineata (fertile fronds); 2, ditto (barren frond); 4, Pteris quadriaurita; 7, Asplenium Trichomanes; 8, Pelloa hastata; 11, Asplenium Adiantum nigrum.——*J. D. M.*—Clematis orientalis.——*Enquirer and Others.*—We cannot undertake to name seeds of plants.——*Marie.*—The leaves look like those of a Begonia, but we cannot tell from such poor material.——*Miss S.*—1, Blechnum occidentale; 2, apparently Polypodium Dryopteris; 3, Davallia dissecta 4, too small to name; ——*H. R. J.*—Sparmannia africana.——*C. R.*—Eriobotrya japonica.——*F. Warr.*—Hoya carnosa.——*E. G. F.*—Plumbago capensis, as far as we can judge from the dried-up condition of the specimen sent. Please put your note in the box with specimens in future——*Zara.*—Epiphyllum of some kind; it wants a warm greenhouse and sandy loam to grow in. Do not give much water unless it is growing fast and flowering.

QUERIES.

4259.—**Mistletoe Seed.**—Where can I procure seed of the Mistletoe? and what is the proper time to sow it?—M. T. L.

4260.—**Manuring Fruit Trees and Roses.**—Will any one kindly tell me when I must manure or mulch my Rose trees which were planted in last October, and were only given enough for their first wants? also if I should treat an old Plum tree in the same way which has borne for the last four years from one to three Plums annually?—M. J. L.

4261.—**Water Lilies.**—I wish very much to grow Water Lilies in a large shallow pan sunk in the ground in my garden, and would like to know where I can procure suitable plants; also if this plan for their culture will succeed.—M. J. L.

4262.—**Gas Stoves.**—I see "Vesuvius" in an article entitled "Gardening Failures" (Jan 29) uses a gas stove in his greenhouse. I shall be glad to have a few particulars of construction, cost, and cost of gas for twenty-four hours.—G. M.

4263.—**Single Delphiniums.**—Will some one please tell me the names, heights, and colours of the best tall single Delphiniums?—F. A. S.

4264.—**Lily of the Field** (Amaryllis lutea).—I should be glad of any suggestions as to the culture of this bulb. I have twice failed with it. It was planted in my lawn and the leaves were carefully protected—F. A. S.

4265.—**Fitting a Coil Boiler.**—I am about to erect a lean-to greenhouse, the inside measurement being 11 ft. 6 in. by 6 ft. 9 in. I have bought a second-hand slow combustion coil boiler to heat it. Will some reader inform me how to fit it up? and whether to put the boiler inside or outside the house?—W. P.

4266.—**How to Put a Damper in a Chimney.**—I should feel oblized if any reader could tell me how I can put a damper in my chimney (which is composed of 6 in. drain-pipes) without taking it down, it being so constructed that to take down a part I should have to take it all down; I want the damper about 5 ft. or 6 ft. from the top of the chimney. The chimney goes up in one corner; the flue, too, is of drain pipes, and I am told they will answer well if I put a damper in.—T. SMITH.

4267.—**Geranium Blooms Falling off.**—I have in a greenhouse, the temperature of which averages 60°, heated by a brick flue, a fine scarlet Vesuvius Geranium, which has twice this winter been covered with flower-buds, but when the latter have got partly grown they turn yellow and die off. Can any one suggest the cause?—P. M.

4268.—**Zonal Pelargoniums from Seed.**—Having given a good deal of my attention last summer to the crossing of some of the best kinds of Pelargoniums, I shall be happy to learn the best and quickest way of flowering them from seed.—T. SMITH.

4269.—**Hyacinths in Glasses.**—I have some Hyacinths in water, some of which have sprouted from the sides instead of, as usual, from the centre. What should I do with them? Also, what must I do with the good ones after flowering? Will they be of any further use, or must I throw them away?—RENRUT.

4270.—**Scented Flowers.**—I shall be glad to have a list of scented annuals and greenhouse plants.—L.

4271.—**Melons.**—Which is the best hardy Melon to grow? and will Munro's Little Heath Melon succeed if grown in a large pot in a greenhouse? I shall be glad of cultural directions, as I have never been able to succeed with them.—L.

4272.—**Gas Stoves.**—"Vesuvius" speaks of a "gas stove with 8 ft. or 9 ft. of 3-in. piping," and evidently a success. I must give up my heating apparatus with hot water and stove, as the smoke is a nuisance to neighbours. I should be glad to know if the gas stove is inside the greenhouse, and what kind, and also the expense, if easy to ascertain. I have pipes and a cistern, and if I could use a gas stove inside the greenhouse it would be very convenient; otherwise, I could have it in the cool house, where the stove now stands. The gas is quite close; in fact within 2 yds. of the greenhouse, which is about the size of the one named by "Vesuvius." The pipes are larger. Any information on the subject of a stove without smoke, and not injurious to plants, will oblige. The stove is only used to keep out intense frost.—LEAMINGTON.

4273.—**Vines in Rooms.**—Will some reader kindly instruct me how to proceed with a Vine? It is in a large pot, and was in full foliage last summer in a room, getting the sun most of the day; it is now like a stick, and the soil appears very poor and dry. When should it be watered? Will it succeed in a similar room? and should it be pruned? Some of the growths are nearly 4 ft. long.—A. W.

4274.—**Glazing Orchard House without Putty.**—Some correspondents recommend, others object to, this. If equally good as putty, it is of course preferable for houses which are to be movable as tenant's fixtures; in fact, they are not practically movable otherwise. But is it equally good? Mr. Rivers says the trees cannot have too much free air. If so, will some one explain how the glass is fixed? Will brads at the bottom and sides of each pane suffice?—C. A. S.

4275.—**House Sewage.**—I have a manure tank for house sewage constructed as engraving on p. 341. Should the liquid from this, which is much diluted with water, be used as pumped up? or should anything be added to fix the ammonia? If so, what? and how?—C. A. S.

4276.—**Coloured Glass for Greenhouses.**—Is there much advantage in using coloured glass, of a green or blue tint, the same as used at Kew, for roofing a greenhouse? and if so, which shade is recommended?—E. P.

4277.—**Paint *v.* Rough Wood.**—For a roughly-built orchard house I am advised not to paint, but to use the wood unplaned. It is stated that the wood will last equally long, and the expense of paint and of its renewal be saved. Is this so?—C. A. S.

4278.—**Planting Late Potatoes.**—Which is the best way to plant late Potatoes?—A SUBSCRIBER.

4279.—**Dividing Orchids.**—Will some one kindly inform me how Orchids are divided? I have both the Cypripedium insigne and barbatum nigrum.—L. L.

4280.—**Mushrooms in Coal-cellars.**—I have serious thoughts of converting my coal-house (a small one) into a Mushroom house, but before doing so I should like advice on one or two points. It is built against the gable end of the kitchen and a grateful warmth is very perceptible from the range on the other side of the wall. The first question is, whether the heat will be too dry for Mushroom culture, and if so, can the dryness be easily counteracted? I should like to know also whether crickets are enemies to Mushrooms, as I have some difficulty in keeping them down in the kitchen, and they make their way through the wall?—ALUMNUS.

4281.—**Mauve and Purple Hollyhocks.**—Is there a real mauve-coloured, and also a bright, purple-coloured Hollyhock, single or double? and if so, what is the names of the double ones?—G. D.

4282.—**Slow Combustion Boiler.**—I wish to purchase a small slow combustion boiler that will only require fuel once every twenty-four hours and that can be depended upon without attention for that time. Can any one recommend me one from practical experience?—H. F.

4283.—**Window Gardening.**—I put some cuttings of Zonal Pelargoniums into 3-in. pots last spring and shifted them in August into 5-in. and 6-in. pots, thinking they would bloom in the winter, but they have never shown any sign of bloom. What am I to do with them now? Am I to let them remain in the same pots as they are? or repot them in the same pots again? I have some old Pelargoniums. When is the best time to cut them down? and when is the best time to repot them? Any instruction relating to the above will oblige.—AMATEUR WINDOW GARDENER.

4284.—**Plants for Greenhouse.**—I shall be glad to know what class of plants would be most suitable for a greenhouse attached to the house 15 ft. by 8 ft., and lofty. It is heated by means of a Calorigen gas-stove, so that frost can be excluded and a moderate heat kept up. More flowering plants have to be renewed from time to time, which is expensive and require re-potting, slipping and changing according to seasons, and this is impossible with the usual suburban gardens from want of proper earth, space, and so on. I want a kind of plant that will look tolerably well through the year. Fuschias and Geraniums I have. Would Lilies be good for the purpose? And can one get a succession of bloom? All bulbs have the advantage of saving stowage, but are, I think, only spring bloomers.—W. T. C.

4285.—**Double White Annuals.**—Chrysanthemum inodorum plenissimum, Clarkia elegans alba fl.-pl., Eschscholtzia californica alba fl.-pl. Are the above worth cultivating to flower in pots in a warm greenhouse in October and November? If so, what is time of sowing and cultivation they require? If not, are there any other single or double white flowers that would flower at that time from seed this year suitable for cut flowers?—L. T. B.

4286.—**India-rubber Plants Frozen.**—During the late frost I had an India-rubber plant in the parlour window, and, although a good fire was kept burning during the day, the thermometer showed it to be a very low temperature in the morning and during the night. The consequence has been that I find the leaves hang down and appear discoloured—brown and darkish, and curled up. I fear this has been caused by the frost. Can I do anything towards its future recovery? I have sponged the leaves with lukewarm water, and given some to the roots; the stem appears alive.—A. R. S.

4287.—**Renovating Ferns.**—I have several varieties of Ferns in my greenhouse which have done very badly this season, although I have treated them in the same way as in other years when they did well. Would it be a good plan to repot them all, shaking most of the soil from their roots? and when is a good time to do it?—ERNEST.

4288.—**Plants for Rockery round a Pond.**—I have made a rockery round my duck pond and would like to plant, in spaces I have left for the purpose, hardy plants of any sort that would grow large and quickly. The spaces are deep and open. Will someone give me the names of some plants that would suit my purpose and the locality—facing south on this north-east coast?—H. G., *Sunderland.*

4289.—**Maggots in Cyclamens.**—I have three dozen of Cyclamens about four years old, which have always done well until this year. I keep them in a greenhouse with about 45° or 50° of heat. I pot them in good leaf mould, loam and sand. Finding the bulbs getting loose, I examined them, and found from six to ten large maggots eating their way into the bulbs, nearly all the roots being eaten away. How can I get rid of them? Also how prevent them in the future?—F. C.

4290.—**Propagating the White Everlasting Pea.**—How and when should this be done?—

4291.—**Geraniums for Bedding.**—I have several dozens of Geraniums stored underneath the shelves in my greenhouse. They are now beginning to grow. When is the best time to take them up, re-pot them, and put them on the shelves to prepare them for bedding out?—GERANIUM.

4292.—**Warming and Ventilating.**—Will "G. S. C.," who writes on this subject in a recent issue, kindly say what are the dimensions of the lean-to which he warms apparently so successfully?—L. S.

4293.—**Clearing Snow from Walks.**—When there has been snow, is it better to clear gravel walks of it or not? I have just been told that frost spoils the walks more than the snow?—A. B.

4294.—**Fence for Espalier Fruit Trees.**—We are going to have an Espalier fence for Apples and Pears. Would it be better to have it of wood or iron?—A. B. [Of iron if you can keep it well painted.]

4295.—**Brewer's Grains as Manure.**—Are brewers' grains useful on flower borders as manure? My garden is a deep, light soil, with a gravelly sub-soil.—F. J. C.

4296.—**Shading Glass.**—How can I make glass pleasantly opaque without making it look objectionable?—SALVIA.

4297.—**Plants for Mixing with Sweet Peas.**—When the ground is fit I intend to sow a good row of Sweet Peas; what other creepers would do well mingling with the Sweet Peas and climbing up the same sticks?—SALVIA.

4298.—**Growing Melons.**—I wish to grow some good Melons in a house about 8 ft. square. The hot-water pipes are only 9 in. below front stage. Would there be room for a box resting on the pipes to grow the Melons in? or how could I manage? The pipes are about the same distance from the walls, which are of wood. The front bench is removable.—A SUBSCRIBER.

4299.—**Australian Seeds.**—Having received the following seeds from Australia, viz., Wattle, or Acacia, Blue Gum, Hurts Pea, some Vines, &c., I shall be grateful for any instructions as to proper management, and also for any information about the growth and flowering, &c., of these plants.—ERIN.

4300.—**Orange Tree in Greenhouse.**—An Orange tree, very weak in pot, has been placed in border of greenhouse. Is it likely to do well there? or is soil, &c., too cold?—ERIN.

4301.—**Pyrus japonica from Seed.**—What treatment is necessary for raising this plant from seed?—ZARA.

4302.—**Agapanthus not Blooming.**—Which is the best time for potting the Agapanthus? My plants root very much, and I fail to obtain bloom.—ROBIN.

4303.—**Sowing Wattle Acacia Seeds.**—How should seeds of the Wattle Tree or Acacia be sown? Should they be steeped in warm water previous to being sown, and how long?—Z.

4304.—**Camellias from Seed.**—Can I raise Camellias from seed on a hotbed? If so, what time of the year, and how should they be treated?—FIM.

4305.—**Annuals.**—I shall be much obliged to anybody who will give me a few hints on what annuals will be likely to succeed in my small garden this year. The soil is very heavy blue clay, with a slight covering of ordinary garden loam. The shrubs have not been planted long, and I should like to know of some showy annuals to sow amongst them to fill up the spaces. I am anxious to have a pretty garden this summer, but I know nothing about flowers. There is a large greenhouse or conservatory attached to the house, but it takes so much fuel to warm it that I have not used it this winter; will it be of any use in raising seeds without heating it in the spring? What am I to do to shade the greenhouse in the summer? Whitewash looks ugly, and I am afraid I cannot get any creepers to grow enough to shade the other plants this summer. I should like to know of a good liquidmanure? I saw the answer to "T." on the subject in GARDENING, January 29, but as I have no stables that recipe will not suit my purpose.—SAPIN.

4306.—**Treatment of Musk.**—I have several pots of Musk, put aside in a cellar last season. What must be done to bring them on to flower well, for in the coming season I have no frame or other means of forcing?—NOVICE.

4307.—**Climbers for Screens under Trees.**—What climbers can I plant to quickly cover the bare stems of trees to form a screen? The tops of the trees are large and spreading, but the bottoms are bare. How should the soil be prepared, &c.?—MATRONLY AMATEUR.

4308.—**Plants Lost through Failure in the Gas Supply.**—Will any reader who is acquainted with the law kindly inform me if I have any claim on the gas company through this supply failing, through the last frost, to heat my greenhouse? I have lost the whole of a valuable collection of plants.—W. W. M.

4309.—**Frost in Ferns.**—I have several Ribbon Ferns, and the frost has effected them. The leaves have quite dried up. Will they ever come round again? or ought I to cut them down? They are now in a small heated greenhouse, temperature 50°.—E. S.

4310.—**White Flowers for Beds.**—Will any of your readers tell me which would make the best white bed: Phlox Drummondi, or Chrysanthemum frutescens (the French Marguerite)? I suppose the Chrysanthemum frutescens, if sown in March, will flower in the summer of the same year.—AGATHA.

4311.—**Rates for Greenhouses.**—I shall be glad if any one will inform me if I am bound to pay poor rates and district rates for a private greenhouse.—J. C. I.

4312.—**Plants for Flower Beds.**—I have five beds on a terrace. Last year we filled them with Sedums, and carried out a sort of carpet bedding, but we thought there was scarcely colour enough. Will some one suggest a few plants that will make a good show for the summer? The situation is rather exposed, and dwarf-growing plants would be best. The beds are oval and about 6 ft. across.—A. H. V.

4313.—**How to Grow Cucumbers.**—In answering "E. H.," I think I had better give a description of my greenhouse, and he will be able to advise me better. It is a lean-to facing N. and N.W. It is 11 ft. long and 8 ft. 6 in. wide. It stands 6 ft. 6 in. high in front, with a rise of about 2 ft. at the back. The door is in the end, and a window is fitted in the top corner to act as a ventilator. I have fitted three shelves on the wall side, which I intended for French Beans. I have also erected a wooden stage 4 in. below the front glass. The heat I obtain from a furnace, built in the end next the door; drain pipes form the flue; I can get the temperature up to 70° at night, and a great deal higher in the day. The pipes run under the stage. I should like to cut Cucumbers by the end of April.—T. BOX.

POULTRY.

THE HATCHING SEASON.

Now that the weather is somewhat milder, and eggs more plentiful, I would advise those amateur poultry keepers who intend to rear a few broods of chickens, to commence operations at once, as chickens hatched now will thrive well, mature early, and the pullets will commence laying in the autumn and continue throughout the winter months; whereas those hatched later in the season will not grow so fast, nor commence laying until the following spring. With those who only keep a non-sitting breed, it will be necessary to procure a broody hen, which can generally be obtained from those who keep the Brahma, Dorking, or Cochin fowl. A sitting box should be in readiness, which can be made of any rough material; those which I use are made of packing cases, or boxes purchased for a few pence at the grocers; they are about 16 in. from back to front, 20 in. high, and 16 in. wide; the fronts are made with a fixed board at the bottom on which is hung a small door, which when closed reaches within 1 in. or so of the top, thus leaving a space between the top of the door and the top of the box to admit light and air to the sitting hen. Place a turf or some mould at the bottom of the box, make the nest of hay or soft straw, and place the sitting box in a quiet outhouse. When sitting, the hen should be taken off the nest regularly every morning and placed in a coop to feed; care, however, must be taken not to keep her off long enough for the eggs to get cold, especially on frosty mornings; ten minutes each morning will allow her ample time to feed, and do no injury whatever to the eggs. When the chicks appear strong enough to leave the nest (which they should do twenty-four hours after hatching), let them be placed in the driest, warmest, and most sheltered spot, if possible near a nice Grass run where plenty of worms may be found. See that they are fed on wholesome food five times a day, but never give them more than they will clear up at each meal. For the first few weeks I prefer feeding them on oatmeal, Spratt's meal, bread crumbs, rice, groats, and a little wheat; boiled Potatoes and scraps from the kitchen should also be used; the more variety the better.—POULTRY MANAGER.

Poultry not Paying.—For the information of one who cannot get his fowls to pay I give the following: I get from the provision dealer bacon cuttings (the cost is 10d. per stone), boil them to a jelly, mix with Indian meal, boxings, and Potatoes or their peelings; this I give hot as their first meal. I also use to the above Brown's aromatic compound; 1s. a tin. In the afternoon I give them Indian Corn and rough Barley mixed; cost 1s. 2d. per stone. My hens have a Grass run, but I also give them Cabbage leaves, which they eat readily. Give them plenty of old lime or burnt oyster shells to pick at, and do not forget the dust bath, as it helps to keep the fowls healthy and free from vermin. Since I have used the above my hens are laying better, and appear to be more able to stand the cold than heretofore.—E. T.

Keeping Poultry.—I have the run of a large brick-yard and meadow, and should like to commence to keep poultry (fowls, ducks, and geese). Will some kind reader please inform me how I ought to begin, and how I can best make it pay? Which of the above named will pay best?—R. C. M.

Diseased Fowls.—Will some one kindly inform me what is the matter with my fowls? They are affected in one eye, and the mouth is all over dried matter in lumps. They have plenty of space both inside their house and out. What can I do to remedy the evil?—R. W.

Treatment of Pea Fowls.—Will some one kindly advise as to the treatment of pea hens when they begin to lay? I find mine suffer from being egg-bound, and we have lost some from this cause. What food should be given them?—L. FRITH.

Temperature for Hatching Eggs.—Having, though now many years ago, had some experience in egg-hatching with an hydro-incubator, we were always very particular about keeping to about 104°. I do not say that we never went lower, but if we did the eggs were spoilt, and if higher, we were likely to have baked chicks. Our trays held 100 eggs, and providing they were all fertile ones, and which you can easily tell after three or four days, we could reckon on having ninety or ninety-five successfully hatched. Once a day the trays were taken out, the eggs turned and wiped with a damp yet warm cloth, taking about 20 minutes.—A. M., *Charlton.*

Fowls in Confined Spaces.—I have a yard about 14 ft. square in which I am desirous of keeping a few fowls to supply me with eggs. I could build a fowls' house in the corner, and make a run 3 ft. wide all round. Will any one who has had practical experience under similar circumstances kindly instruct me how to commence? What kind of fowl will be the best? Also should I get a broody hen and a sitting of eggs? or buy what pullets I want? How many could I keep in such a place? The run would be about 10 ft. long after I had built the house and 3 ft wide. The yard gets very little sun, but it is light and open. Is this a drawback? Any practical hints will be welcome.—S.

Leghorn Fowls.—Can any reader give me any information as to the merits of Leghorn fowls. Do they thrive well in confinement? Also are they good layers? and are the white preferable to the brown? I should like to have the practical experience of some one who has kept these fowls.—COCKEREL.

Poultry Farming.—I have got half an acre grass land, which I could enclose with hurdles 3 ft. high. I want fowls that will not fly over; if they did so they would be in my neighbour's cornfields, and that would make things unpleasant. If I was to get Cochin China or Brahmas, could I keep them enclosed? or can any other breed be recommended?—W. B.

Best Fowls to Keep.—In answer to "F. C. W. R.," I should suggest light Brahmas. I have myself tried all sorts, both in confined spaces and with grass runs. I find the Brahmas are most profitable, and lay the best eggs. —W., *Sydenham.*

Fowls Plucking each Other.—Will some reader tell me how to prevent my fowls plucking each other? I have twelve in a run of 20 ft. square. I give them flesh meat in the shape of greaves; and raw turnips now I cannot get green food. They are fed twice a day; hot pudding in the morning, and corn in the afternoon. I have changed the cocks three times, as they begin plucking him first. Any hints will be welcomed.—E. WILMOT.

BEES.

Bees in Winter.—"D. R." must feed his bees as soon as the frost and snow is gone, but until then stop up the entrance, or he will lose many, for if they get out in this severe weather not many will get in again. In September he should have fed them more liberally, seeing they had to make comb as well as to provide a store of food for the winter. Not less than 28 lb. or 30 lb. of syrup should be given in such a case. In future, I would recommend him to super and not nadir; both bees and keeper will be better pleased.—APIARY.

—— These last few days since the snow has been lying thick on the ground my bees have flown out of their hive, settled on the snow, and perished from the cold. Can any one tell me the reason of this? The sun, from about eleven o'clock till three, is very warm, and shines full upon the hive which faces due south. The stock was a very strong one, and I was told when I bought it in the autumn that it would require no feeding.—HASTOE.

Bee Keeping.—Will any practical keeper kindly oblige with the name of a thoroughly good and exhaustive work on bees, with publisher's name? Also the best proved form of hive, and where to be obtained?—MELITUS.

AQUARIA.

Stocking Aquarium.—First get some river sand and scald it to kill the filth, and wash it well with cold water; then put the aquarium to a desired depth, say 1½ in., on a flat bottom. Then plant in the centre Nymphæa alba or Nuphar lutea; round the sides Fountanalis antipareca, Myriophyllum spicatum, Hottonia palustris, and any of the Charas, but plant the largest next the window, to shade the light. Round the centre plant Vallisneria spiralis, Caryophyllum demersum, Helosciadum nudiflorum, and Potamogeton crispus. The following, as they float, make a good addition to the former. Utricularia vulgaris, U. minor, Hydrocharus morsus ranea, Stratiotes aloides, Lemna polyrhiza. The last named, with its numerous roots, adorned with a rich purple hue, underneath their shady leaf, which makes it a most esteemed plant for the aquarium. I would not advise anyone to put more than three small fish along with four snails, in a 12-in. aquarium, as both fish and snails, in my opinion, make an aquarium unsightly. I may here ask, what is there more pleasing than to watch the movements of the Water Spider (Argyroneura aquatica) springing to and fro through the openings of a well established and planted aquatic forest?—J. J. N.

4012.—**Making an Aquarium.**—Can any reader give me instructions how to make an aquarium? Can the glass be fixed in such a way that the water will not come in contact with the wood? and is there any special putty required? Any information will be thankfully received by FISH.

HOME PETS.

Insects in Birds.—From "Myra's" description I should say her Virginian nightingale has red mites; this is very common in cage birds. If "Myra" examines the crevices of the perches in its cage she will probably find them full of mites, as they generally attack the bird at night and remain during the day in the perches and corners of the cage. Put the bird in another cage and then remove the perches, pour boiling water on them, and let them remain in the water for a short time; do the same to the cage and tray. Boiling water is the best thing to destroy these insects. A little of Keating's insect powder might be put on the bird; it will not harm it; I have often done it to my birds. She must take care the powder does not get into the bird's eyes. But I think that the mites will be found in the cage, and only come to the birds at night. Repeat the process of boiling the cage about every six months; give the bird a bath every day, as these birds delight in washing. I have one which comes out of its cage, flies about the room, and takes its bath in a shallow pan. I have had him three years; they are most intelligent birds, and get very tame.—F. T.

Love Birds.—I brought my love birds from Madeira seven years ago, and they are quite well and lively now; I keep them warm and out of draught in winter. The cage is a small waggon-shaped wire one with wood bottom; seed boxes outside; in size about 10 in. by 7 in.; cost 4s. 6d. at a cage shop. In the winter the cage is covered over at night with a flannel covering, the perches are kept dry, so is the cage, cleaned daily, and fresh bird sand put in. As regards food, I give canary seed and water daily, and in summer a little watercress.—C. J. F.

Preserving Skins of Birds.—Scrape and clean your skins and then rub over them the following arsenical soap: To 4 lbs. of white curd soap add one pound of arsenic and 1 oz. of camphor. Cut the soap into thin slices and dissolve in one pint of water. When the soap is melted add the arsenic and camphor, stirring all well together, and boil again till a thick paste is obtained. Pour into jars while hot, and when cold tie down carefully with bladder. This will keep for years.—J. MARTIN.

Changing the Colour of Canaries.—I should advise "Mervyn" (page 518) not to try cayenne pepper for darkening canaries, as in a year or two it kills them; the only way to make them rather darker is to give them plenty of Rape seed, mixed with canary seed, boiled carrot, and now and then yolk of egg, boiled hard. But there is no means of healthily changing the colour of a light canary.—P.

Thrush not Singing.—I have no doubt that "Dolly" will be able to procure a "bird organ" of a new kind in the Lowther Arcade, Strand. The prices range from five shillings. I have known birds to be completely trained to sing by means of such an instrument, but cannot say how far it would succeed with one which had discontinued its song. The cage should be covered with a non-transparent cloth when the organ is used, so as to concentrate the attention of the bird upon the sounds.—SYMPATHISER

FINE-LEAVED GREENHOUSE PLANTS.

MANY who only possess a cool greenhouse are under the impression that there are comparatively few fine-leaved plants that they can grow, supposing that most of these require a stove or intermediate-house for their cultivation; yet this is by no means the case, as there are numbers of handsome variegated-leaved plants, in addition to those with green foliage, that vie in their elegance of form, or the beautiful colours of their leaves, with many from tropical countries. Amongst the most beautiful of the variegated-leaved subjects suitable for a greenhouse is the Japanese Eurya latifolia variegata, a plant almost hardy in the south of England, but particularly suited for greenhouse culture; the centres of the leaves, which are about the size of those of an Orange and similar in substance, are bright green, margined with white when fully matured, tinged with red whilst young; the habit of the plant is not unlike that of Croton variegatum, to which it is quite equal in appearance; it is easily grown, succeeding well in either peat or loam, to which a moderate amount of sand has been added. Drain the pots well; as it is a free rooter, care must be taken that it never wants for water. The plant is of a naturally pyramidal habit, branching freely without much shoot pinching. It is little subject to insects, but should be syringed freely with clean water once or twice a week during the growing season to keep it free from red spider, which will sometimes attack it. Whilst small it is a capital plant for a sunny window. The gold and silver variegated forms of Aralia Sieboldi grown to single stems are handsome plants; they have ample palmate foliage, thrive well in any ordinary soil, and are best raised from cuttings taken off with a heel from plants that have been headed down; they strike readily at any time of the year when procurable 5 in. or 6 in. in length, inserted in small pots in sand, kept moist, and covered with a bell-glass in a little heat. A. reticulata is an elegant-growing, handsome-leaved species, of much more slender habit than the preceding; it does well in peaty soil, not requiring so much root-room as the above-mentioned kinds. Aspidistra lurida variegata is an evergreen plant that attains a height of 2½ ft.; the leaves are lanceolate in form, stout and persistent, marked longitudinally with broad bands of green and white in about equal proportions; it is easily increased by division of the roots at any time when not in active growth; it will succeed with the simplest treatment in ordinary garden loam. It is one of the best room plants, the foliage remaining in good condition in an ungenial atmosphere longer than most plants; when so used it should be syringed and sponged occasionally to free it from dust. Coprosma Baueriana variegata is another easily-grown variegated plant of a somewhat soft-wooded character; for decorative purposes it looks best grown up with a single shoot tied to a neat stick, stopping it from time to time to induce it to break outside branches, which also occasionally should have their points nipped out to produce a sufficiently compact habit; it strikes best from comparatively soft young shoots, produced from branches that have been stopped, taken off with a heel, inserting them, half-a-dozen together, in 4-in. pots in sandy soil in a little warmth, kept moist and covered with a propagating glass; any common soil, to which has been added a little leaf-mould and sand, will answer its requirements. Phormium tenax variegatum (variegated New Zealand Flax) is a tall-growing, evergreen, herbaceous plant, with leaves not unlike those of the common English Iris; they rise to a height of 4 ft. or 5 ft., and are striped longitudinally with yellowish-white over about one-third the surface, the rest green. From its erect habit of growth it looks well mixed with Pelargoniums, Fuchsias, or other ordinary greenhouse plants, for which purpose it is much better confined to moderate-sized (say 8-in. or 10-in.) pots than when grown in masses. It is easily managed, succeeding perfectly in loam, to which add a little leaf-mould and sand; it is increased by division of the roots, which operation should be performed before the growth commences in the spring. Amongst various other handsome green-leaved subjects suitable for greenhouse decoration may be named Acacia lophantha, a plant with elegant Fern-like leaves, which may be grown to a very large size, but for the purpose under consideration amateurs will find it much more useful confined to a single stem in pots from 6 in. to 8 in. in diameter; it is one of the freest of free growers, doing well in either sandy peat or loam; it can be increased from either seeds or cuttings put in now in a hotbed and kept on growing through the autumn. Aralia crassifolia, A. leptophylla, and A. quinquefolia are all handsome plants; they, too, look the best confined to a single stem, as the leaves are of a persistent nature. If kept clear from insects they will remain fresh down to the base of the plants until they have attained a height of from 3 ft. to 5 ft.; they are not quite so free to strike as some things, but with these, as almost everything else that does not root readily, amateurs will succeed the best by making cuttings of the young shoots that break after a plant has been

GREVILLEA ROBUSTA, AS GROWN BY BECKWITH FOR MARKET.

partially cut down. When these are removed entire from the old wood that has produced them, that is, taken off with a heel, as is understood by this process, few will fail to root; put in small pots, kept warm, and a little moist, and covered with a propagating glass, they will make good plants in a single season. Dracæna indivisa is a plant of large growth, but one of the most elegant subjects in existence, suitable for occupying a central position in a greenhouse. If small plants be obtained in spring, and moved on into larger pots as they require it, they will go on for years until they have attained a height of 8 ft. or 10 ft. Evergreen plants of this sort must never be allowed to want for water at the roots. This Dracæna should be well syringed on both upper and under sides of the leaves once a week during summer, to prevent the attacks of red spider, to which it is somewhat liable, and which, if allowed to gain a footing, will soon affect the bottom leaves, so as to make the plant bare at the base. Grevillea robusta, which we now figure, is a Fern-like plant of the most elegant description, and will succeed well in every way, both as to propagation and after management, if treated as recommended for Aralias. It may be also readily raised from seed sown in heat, and potted on in good rich soil. The seed, however, must be new, or it will fail to germinate. This Grevillea is an excellent market plant; it is grown in large quantities by Messrs. Beckwith & Sons, Tottenham, who sent us the plant from which our illustration was prepared. The plant in question was about 3 ft. high, well clothed with large green Fern-like foliage, and it was in a 6-in. pot.

FRUIT.

STANDARD BLACK CURRANT TREES.

For the information of the uninitiated who are wishful to produce large fruit for show or table, the following method for rearing young Black Currant trees may be useful: Eight years ago a friend presented me with half-a-dozen young Black Currant trees. The stems had a Vine-like tendency, and grew long and wiry. They were immense croppers, both for quantity and size of fruit. Our garden had a south aspect, and the soil was light and friable; and as Black Currants require plenty of strong nourishment, to supply this want we gave the trees several barrowfuls of strong cow manure, completely covering the roots for 3 ft. round each. The result was a prodigious growth of new wood and a heavy crop of fruit. Having been so far successful, it occurred to me that an old gardener some time before had said that if I took the stoutest stems of one year's growth and stripped them of the whole of their buds, except about three or four at the bottom and five or six at the top, taking care not to injure the bark any more than could be helped, I could rear a standard Black Currant tree that would produce larger and bolder fruit. I tried the experiment with very satisfactory results. Many people have complained of disease in Black Currant trees—what seems to be the result of inoculation by insects, producing little bolls on the stems where the bloom-buds should be, and taking all nourishment from the trees. In no instance do I remember the standards suffering from this disease, though my Black Currants that come up several shoots from the one root, or grown in the ordinary way, are suffering at the present time. There appears to be no remedy for this disease but extermination and commencing again with clean young plants. To keep Black Currant trees in good bearing condition, there should be a good supply of strong manure applied to the roots. Especially beneficial also is liquid manure from either stable, shippon, or ashpit. A good screen may be made of Black Currant trees by nailing them to a row of stumps and rails in the direction required; and in this position, especially in the centre of a garden, they will do well. Great care must be taken to thin out all old and poor branches, as these impoverish the young bearing wood. If any inducement need be held out for the encouragement of the culture of this delicious fruit, it is only necessary to say that it has many medicinal properties, not the least of which is as a cure for a severe cold; and as a jam there is perhaps nothing to surpass it. To propagate the Black Currant it would be well to put the slips in the ground not later than March, or at the end of summer, say end of September. Avoid as much as possible digging about the roots, and rather spread or pour the manure on and about the roots. No digging should be done after September or October, and that more to clear away grass roots and weeds. Should any of the small fibrous roots be cut, they will then have time to grow by the following summer. And, in conclusion, I should like to say to all who are about to plant young trees, get the best kinds known, consult any first-class nurseryman, and do not be afraid of paying a little more for the better class of plants. As in breeding fowls, so in growing any kind of fruit tree, to pay a little more at first is cheapest. Black Currants grow well near a drain, or ditch, or sewer. — Cough Quietus.

Scale on Vines.—I was troubled last spring with a quantity of scale on my Vine. I bought ¼ lb. soft soap and ¼ lb. of sulphur and thoroughly mixed them together, and then with a soft brush and a little warm water made a strong lather and brushed it well into the rods, and I have not seen the slightest traces of scale since. I always keep some of the mixture by me, as I find it a good remedy for many pests.—J. J. C.

Top-dressing Fruit Trees.—We had some Peach trees in a house which made very weakly shoots, and their general want of vigour indicated a deficiency of nourishment at the root. Early in spring all the soil was removed from the roots for more than 1 ft. below the surface. For this was substituted a rich mixture of loam, cow manure, and old lime rubbish, one barrowload each of the two latter being mixed with three of the former. Shortly after the trees began to grow it was evident that they were taking advantage of the fresh material, and by the end of the season the wood was three times stronger and healthier than it was at the end of the previous one. These trees are more promising than any of the others, and we are so well pleased with them that we have done every one of our wall trees in the same way this winter.—C.

Pruning Gooseberries.—I never prune Gooseberry bushes until they are bursting into leaf, and yet we always have heavy crops. It is a good practice to get work as forward as possible during the winter; but some discretion should be exercised as to the right and wrong subjects to be dealt with, or more harm than good may ensue. As regards keeping bullfinches from destroying buds, the best remedy is powder and shot. All kinds of guards except close netting are useless.—J. H.

VEGETABLES.

How to Grow Horseradish.—This, being difficult to kill or eradicate, is generally relegated to some out-of-the-way corner, and seldom has justice done to it in the way of cultivation. There is always a demand for it, and in deep, light soil, if well managed, it would prove a paying crop. The land should be deeply worked, and if manured the manure should be buried deeply. Make holes with a crowbar in rows 18 in. apart and about 12 in. or 15 in. asunder in the rows; the holes should be at least 16 in. deep, and the sets should be dropped into them. The latter should consist of stout pieces of roots 3 in. or so long, either with or without the crown bud, and the holes should be filled up with fine soil or shifted ashes, the latter being preferable. Another plan is, when taking up the crop, to save all the long slender roots that are not large enough for use, to trim off all the small fibres, make holes with a crowbar of sufficient depth and at an angle of 45° or so, and drop the roots in so that the crowns are beneath the surface, filling in with ashes or burnt earth. Planting the roots in a slanting direction enables the cultivator, if he feels disposed, once during the growing season to take the crown of leaves in his left hand and draw the root up, so that the pressure is brought to bear in that direction in which it has been planted; the strong fibres that generally start away just under the surface may be cut off, and the crown of the plant returned to its former position and pressed down with the foot. Plant any time in March.

How to Grow Cucumbers.—To grow fine Cucumbers, the plants require to be grown under glass, either in low flat houses, pits, or in frames placed on hotbeds. A low house or pit, heated by means of artificial heat, will be found the most useful, especially in early and late forcing, as at that time they require a deal of attention, as their enemies are more common, and artificial fertilisation will have to be more practised. In summer their culture is far less difficult, as mildew and other pests are less common. They do not require an exceedingly fine soil. Some turves chopped up, leaf-mould, loam, and some well-rotted manure mixed up makes a very suitable compost. In raising the seeds it is a good plan to treat them the same way as Vegetable Marrow seeds are planted in pots—that is, placing two seeds in a small pot, placing them in an upright position. When they begin to show the rough leaf, pull out the weakest, leaving the strongest plant to occupy the pot. By raising the seeds in this way, one shift more will be sufficient until finally planted out. Thus treated, the seedlings do not experience the slightest check; keep them well up to the glass, in a temperature of 70° to 75°, but when in full growth a higher temperature may be allowed; stopping and tying must be attended to, and over-cropping must be avoided; keep a moist atmosphere, and never allow the plants to get dry or flag from want of water.—Kirkton.

Mustard, Cress, and Radishes.—Mustard, although not required in such quantity for salads as Lettuce and Endive, is still very useful, especially in the winter and early spring. Its cultivation is so simple and well-known as not to require further notice than to say that at all times of the year it should have a rich soil, which not only grows it much crisper, but less hot and pungent. In the winter, in forcing, the soil should be changed in the boxes every time fresh seed is sown. Cress is not so much in request as Mustard, but some people like the flavour of it a little. It is not so easily grown as Mustard, but requires similar treatment; the plain-leaved is the best. Radishes are indispensable through

French Olive-shaped Radish.

a great portion of the year. These should be sown out-of-doors in sheltered situations at the close of the year in dry, well-manured soil, the seed being covered with litter, which is allowed to remain on until the seed has vegetated, when it must be taken off every mild day and replaced in the evening. As soon as the first sowings appear above ground make a second, treating it similarly; the third sowing will possibly not require covering with litter. The earliest sowings should consist of any of the long early kinds, and may be followed by the scarlet and white Olive-shaped varieties, which, when the seed can be had true, are far superior to either the Turnip or the long varieties—that is, when they are grown in rich soil, with sufficient room to prevent their being drawn, and with plenty of water in dry weather, so as to bring them on as quickly as possible, for this is the principal point in the cultivation of a good and tender Radish. To have them in good order they must be sown every ten days through the summer, and in hot weather the seed will require plenty of water to make it vegetate. At the commencement of the year a sowing should be made on a slight hot-bed. The frame, unless a very shallow one, should be filled up inside with the fermenting materials to within 1 ft. of the glass; on this should be put 6 in. of soil, in which sow the seed. It is necessary to keep them thus near the glass, because, if severe weather should follow when they are up, enough air cannot be given to prevent drawing, which spoils them.

To avoid this, they must be thinned whilst small, so as to allow them sufficient room; a successional sowing in frames should be made every three weeks, until the middle of March, after which the outside crops will come in. To succeed the outdoor sowing in the autumn it will again be necessary to resort to frame culture, sowing every month from the middle of September to December; for these early and late sowings, either in frames or the open air, the Olive varieties are little inferior to the short-topped, long-rooted kinds. My own practice has been to mix the seed and sow both together. Where there is no convenience for growing Watercress, the American or land Cress will be found useful in the spring, making a couple of sowings the first and third weeks in September, and putting the seed in a dry warm border in rows 1 ft. apart, with a little Corn salad, which may be similarly treated as to soil, situation, and distance apart.

MY GARDENING FAILURES.

"Disappointment" (Jan. 8) is not necessarily an ass because he has made a few failures in his first attempts at town gardening, very little instruction in that branch of horticulture being available for those who may desire it. The smoke, dust, gas-laden, and exhausted air of a crowded town are unavoidable, but curable causes of failure are mainly two: a bad state of the soil, and an unsuitable selection of plants.

Various causes combine to render the soil of a town garden liable to become sour and stagnant, and unfit to support vigorous plant-life; and this can only be remedied by frequent turning over and exposure to frost, air, and sunshine, and the addition, as often as possible, of fresh, healthy soil from a country district.

The soil in the greatest part of the northern and southern districts of the metropolis is a stiff, intractable clay, which requires a great deal of preparation and several years' cultivation to make it suitable for most garden plants; and when the soil has been cultivated, either as old garden gravel or as market gardens, the whole of the surface soil which is of any value is often carted away and sold before building operations are commenced.

Where that has been done a fresh soil must be provided before anything can be expected to succeed; but if the soil is sweet and good, and the situation open and sunny, and not too much enclosed by buildings, a good display of flowers and plenty of healthy foliage may easily be obtained. Scarcely any of the flowers with which Londoners are familiar in a cut state can be grown, and as few of those which are usually offered for sale as growing plants; but many showy things will produce respectable flowers, and a few can be grown as well as in the open country. One difficulty in a town garden is

Manure.—Artificial manure does not answer so well as well-rotted stable dung, but there is always the difficulty of laying it up to rot. The best way is to keep two frames going, one with fresh manure, and the other half spent, and by the time the heat is entirely out of the dung it will have almost ceased to be offensive, and can be laid up and covered with a sprinkling of earth till required.

In stocking a town garden, reliance should be placed upon those plants which have been proved to do well, and others tried experimentally, and with the full expectation of five or six failures to one success. In buying, observe as three golden rules, never to be departed from: (1) buy all your plants from a good nursery, and one as nearly as possible on soil of the same nature as your own, so that the plants may experience the least possible change in moving; (2) never buy plants in bloom, or with their bloom-buds showing; (3) raise everything you can from seed; there is a considerable amount of adaptability in plants, and it is better to have flowers that an expert or a florist would laugh at than none at all.

As town gardens are usually too deficient in free, fresh air, trees should be avoided; the fences and walls can be covered with Ivy, Virginian Creeper, common Jasmine, and Vines, all of which do well in towns; in open sunny situations, the blue Passion-flower, Wistaria, Laburnum, and the common wild Clematis or Virgins' Bower will all thrive and flower freely. Fig trees also do remarkably well, even in confined situations, and Apple, Pear, and Cherry trees might be grown for their cheerful appearance when in bloom, irrespective of fruit. The common German Iris or Blue Flag is a capital town plant, and there are many splendid varieties of it which would doubtless do as well if tried. In shady nooks Solomon's Seal and the common Male Fern thrive luxuriantly; and for hot sunny corners Aspidistra lurida is suitable. In positions half-shaded the common blue Squill or wild Hyacinth thrives well, and of it there are both white and rose coloured varieties. The Day Lily is a good town plant, and the common Orange Lily will thrive almost anywhere if it gets plenty of sun, with good drainage, and the addition of sand and peat to the soil; the White Lily may be planted in prominent situations; and the Everlasting Pea may be allowed to trail over a rockery, or trained up a wall. Of

Dwarf Spreading Plants, the Periwinkles (Vinca major and minor), both white and blue, may be allowed to trail over a shady border; their flowers are very graceful in form, and last well when cut; the Creeping Jenny thrives well and flowers freely if allowed to run, and Lily of the Valley does nearly as well in towns as in the country. Of

Rock Plants, London Pride, Stonecrop, and Sedum spectabile will answer; and if there is a particularly breezy and sunny spot, white Arabis and purple Aubrietia may succeed in light soils or otherwise if provided with a light soil to root in. The broad-leaved Saxifrages, S. cordifolia and S. crassifolia, look well and often flower, and Tradescantia virginica can be depended upon to produce its deep blue, triangular blossoms; the last does well in an ordinary border, but the Saxifrages are better on a rockery unless the soil is light and well drained. For the back of a border, the Evening Primrose is a good tall plant. Of

Flowering Shrubs, the Lilacs do fairly well, as well as the flowering Currants (Ribes). Of

Florists' Flowers, the Hollyhock succeeds fairly if the situation is not too confined; the Dahlia also succeeds, while the Chrysanthemum family can be grown as well as in the country; the new early-flowering kinds are said to succeed quite as well as the older varieties. Of early-flowering

Bulbs, the Tulip and the Crown Imperial will succeed if the ground is well mixed with peat before planting. Common yellow Narcissus also does fairly well. Of other spring flowers not already mentioned, Daisies, Pansies, and Primroses may be made to succeed with care; the Pansies should be raised from seed. Gladiolus Brenchleyensis and gandavensis will answer in light, rich soil in a sunny place; they should be planted early.

Annuals, especially quick-growing sorts, may be depended on for a show of colour, but the soil for them must not be too rich. Nemophila insignis, Collinsia bicolor, Gilia tricolor, Bartonia aurea, Virginian Stock, Coreopsis and Convolvulus minor, Malope grandiflora, and Godetias of sorts, Clarkias, Sweet Peas, Cyanus or Blue Cornflower, Marigolds (common French and African), and annual Larkspurs, will do in most places. Tom Thumb Nasturtiums make a fine show in a sunny place in a poor soil; where the soil is rich they can be sown in pots and sunk along the borders. Crimson Flax is a good showy annual for a rich soil. Of hardy climbing annuals, Convolvulus major does well in hot seasons, and Tropæolums also do well.

Half-hardy Annuals.—Asters, Zinnias, Ten-week Stocks, and Phlox Drummondi are the most likely to be successful; and Dianthus Heddewigi and Indian Pinks do well in light soils and are very showy. Biennials are apt to perish in muggy weather, and are best treated as annuals, that is, sown in a little heat early in the season, hardened off (gradually accustomed to the outside air, avoiding any sudden change), and planted out as soon as the frost is out of the ground. Treated in this way, Canterbury Bells and Sweet Williams will flower the same season. Antirrhinums flower the first year raised from seed in the same way; they require a sunny place and a light soil containing plenty of lime. Of

Perennials, which are worth trying, those most likely to succeed are the Lilies, Irises, Phloxes, Pyrethrums, Œnotheras, Columbines, Delphiniums, florists' Ranunculus, and Anemones; the last two can be planted as dry bulbs in spring. These all disappear almost entirely in winter, and so escape the evil effects of fog. Nurserymen in the neighbourhood of London, who keep stocks of hardy plants, make up collections of plants suitable for towns, and one of these would be a good investment for an amateur who was determined to master the difficulties of town gardening.

One difficulty in towns is the unhindered ravages of vermin, caterpillars, woodlice, and all the rest of them, which increase and multiply with impunity; in the absence of the whole tribe of insect and vermin-eating birds these must be continually trapped and destroyed in every possible way. Dirty flower-pots filled with straw or paper shreds and Potato parings are good traps for creeping things; slugs and snails can be caught in the same way, the flower-pots being placed along the borders bottom upwards and raised a little from the surface to allow a shell-snail to get underneath; caterpillars must be hand-picked. With regard to

General Cultivation, plants in towns require to be kept moving; it is injudicious to induce rapid growth while there is a chance of frost, but as soon as warm weather sets in they may be set growing if they do not start themselves. Sulphate of ammonia is a good stimulant in the proportion of a tablespoonful to a pail of water. It should only be used when plants show a tendency to hang back. Genuine Peruvian guano is also a good stimulant in about double the proportion to the water, and does not tend to impoverish the soil when used frequently as sulphate of ammonia does. A powerful garden engine is almost a necessity in a town garden; without it it is very difficult to keep the leaves and stems of plants clean, and if allowed to get dirty many become weakened and die.

A Greenhouse is only a vexation unless properly constructed. A regular supply of fresh air, heated before entering the house, must be arranged, as well as ventilators for carrying off the foul air, without creating a back draught. If the air before entering the house is strained through cotton wool it will be a great advantage to the plants. "Disappointment" would seem to have kept his house too close. Plants generally run up tall and weakly if not supplied with plenty of fresh air. Plants in pots which are offered for sale in full bloom in London have usually been forced, and are a source of frequent disappointment to purchasers, who expect them to remain for any length of time in the showy state they are in when purchased. Such plants have been subjected to the most skilful treatment to make them produce a great quantity of bloom at one time, and require to be rested in cooler houses when that is over to recover themselves after the extra exertion they have been put to. A greenhouse should be stocked with young plants from a good nursery, and if ordered all at once from a respectable firm, leaving the selection to them, and stating the nature of the greenhouse and the temperature that can be maintained, a suitable selection will be supplied at a cheaper rate than if the plants were purchased separately. I have recommended peat to be mixed with the soil in certain cases, as it can be more easily obtained in London than leaf-mould or loam from rotted turf, which would answer equally well where obtainable.

With regard to "Disappointment's" particular troubles, failures in purchased plants occur through improper planting; the roots should be spread out as much as possible, and fine soil sprinkled over them, and the soil pressed firmly down and round the plant with the hands; the soil should not be wet and adhesive, and if dry a good soaking should be given to each plant, and no more until the soil is almost dry. I find it a good plan to place an inverted pot over small plants for a few days if the weather is dry after planting, leaving the hole open for air. Autumn is the best time to plant perennials, and they should be put in early. The roots of plants do not seem to push out in autumn, winter, and spring in towns in the vigorous way they do in the country, most likely owing to the blue and violet light, which is the most conducive to plant growth, being intercepted by yel-

low fogs; it is therefore important to have everything well established in the autumn. The last three or four summers have been very unfavourable to the growth of plants in the south of London; owing to the great prevalence of light winds from the north half of the compass the whole of the smoke has been driven in that direction, making the south districts more smoky than the heart of the city. The last winter was likely to kill a great number of bulbs; I have had Tulips killed in less severe weather in much more favourable soil, in a less smoky district than Camberwell, while those of the same lot which survived through being a little sheltered, stood last winter in the country, in a stiff badly-drained soil, and flowered splendidly.

J. D.

TOWN GARDENING.

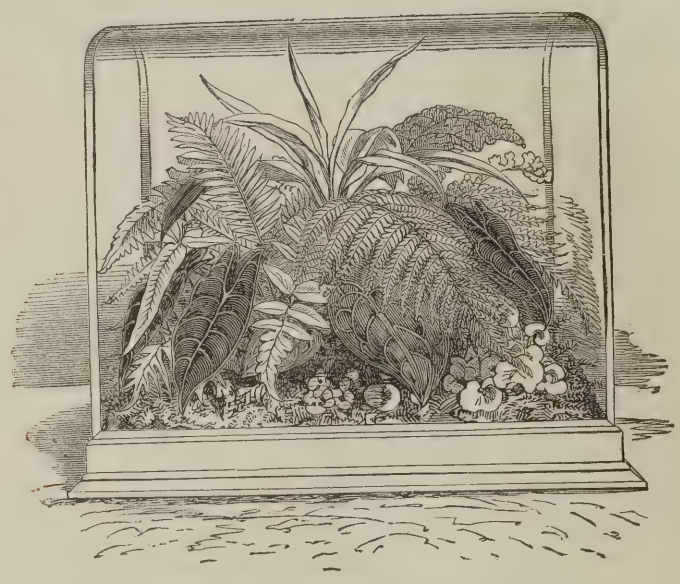
WINDOW GARDENING.

Window Cases.

There is one other branch of window gardening which, though it cannot be indulged in quite by every one, is yet within the reach of most people if they make up their minds to it, and which is, moreover, much the prettiest and most successful arrangement we know of. We refer to the use of window cases. These may be fixed either inside or outside of the sash, but for several reasons (light, saving of room, &c.) are better outside. Being, in fact, a miniature greenhouse, a very large proportion of the soot, smoke, and dirt, that would otherwise be deposited on the leaves, &c., of the plants is entirely prevented, thereby keeping them not only far cleaner and brighter in appearance, but far more healthy and vigorous as well. Moreover, an artificially moist and warm atmosphere can be maintained within a glass case (which is a wonderful advantage), rapid evaporation is prevented, and there are other points favourable to success which need not be enumerated.

It is true that good window cases are expensive to purchase ready-made, but with many people moderate expense is not an object, and some extremely elegant designs can now be obtained. But it is by no means difficult to make a case quite good enough for ordinary purposes, and even if it must be plain, yet if well done it may be neat enough to please even a fastidious eye. Any handy man with a little knowledge of carpentry and a few tools, some strips of red deal, and a few sheets of glass (which only cost 2d. a foot cut to size), can produce a neat and useful affair for a few shillings. The bottom of the case should consist of a strong wooden box or tray, as long and as wide as the space to be filled, and from 6 in. to 8 in. or 9 in. deep. This should be made of the best red deal, 1 in. or 1½ in. thick; upright strips of well-seasoned wood, also 1¼ in. or 1½ in. square, and rabbeted or grooved on two sides to take the glass, should be fixed at the corners; crossbars, also rabbeted or grooved, must be fitted to connect the upper ends of these, and the top should be made sloping at an angle of 30° to 45°. We think that a flat, sloping top looks quite as well as a rounded one, and it is much less expensive. The wooden tray at the bottom should have an inner one of metal, preferably zinc, constructed to fit it exactly, to hold the earth and plants, for, as paint is not admissible inside, the wood would soon decay, and both the metal and wooden tray should have plenty of holes corresponding in the bottom to allow surplus water to escape. It is better to have a short piece of metal pipe soldered into each hole, and running through the wood below, but not projecting much below, so as to keep the wooden bottom quite dry.

The case should be constructed just high enough to meet the junction of the upper and lower sashes of the window frame. Unless it is made with a separate front (towards the room) and a door, the upper rail of the case should not be in any way fixed to the lower rail of the upper window sash (which is of course outside), but only just fit against it as closely as possible, so that the upper sash may at any time be pulled down to admit air into the room. In this way the case will only have the front (outside) and the two sides glazed, and the inner side will be formed by the lower window sash, which, on being pushed up, will afford entrance to the case; or the case may be made entirely separate from the window, with a door on the inside. The former plan is, however, more economical and convenient. In any case, some aperture must be provided at the top that may be opened to admit air. In the plan first described, almost enough will be afforded by pulling the upper window sash down a few inches, as the glass falls back from the level of the rail. This will be seen at a glance, and as a window case does not require a great body of air admitted into it, it will be sufficient, but of course the upper part of the window will be open at the same time.



Window Case of Ferns and Fine-leaved Plants.

Plants for Window Cases.—In considering the class of plants suitable for such glazed cases, it may be mentioned that such things as Pelargoniums, Fuchsias, and others of the same character may be kept in them for some time, and would be preserved in beauty far longer in this manner than if exposed to the air, but could scarcely be continuously grown in such a situation, except perhaps Fuchsias, which would do well with care, but it is preferable to grow such plants as require but a small amount of air, for the more air you admit the more soot and dirt comes with it, so that we advise a selection to be made from the following list, all of which will do well, though they will require some considerable amount of care bestowed upon them in such confined quarters, and under such artificial circumstances. All are effective and pretty, and some extremely beautiful.

s Achimenes, in variety
Aralias (small)
s†Begonias, both tuberous (flowering) and the Rex type (ornamental foliage)
Cephalotus follicularis (New Holland Pitcher-plant)
s*Darlingtonias (Californian ditto)
s*Dionæa muscipula (Venus Fly-trap)
†Dracænas (small)

s*Ferns.*—the most suitable kinds for a case are :—

Adiantum æthiopicum	†Onychium japonicum
† ,, Capillus-veneris	Polypodium plumosum
† ,, cuneatum	Polystichum triangulum
,, hispidum	Pleopeltis nuda
†Asplenium bulbiferum	†Pterio crenata
,, flabellifolium	† ,, cretica
,, monanthemum	† ,, serrulata
Davallia Novæ-Zealandæ	,, ,, cristata
Doodia aspera	*Todea pellucida
,, media	* ,, superba
Lastrea acuminata	s†Gloxinias
,, glabella	†Isolepsis gracilis
Lomaria lanceolata	*Mimosa pudica (Sensitive plant)
,, Herminieri	
Niphrobolus lingua	

Palms.—The most suitable kinds are :—

Chamærops excelsa	Rhapis flabelliformis
,, humilis	*Sarracenias (Side-saddle plants)
Cocos Weddelliana	s Selaginellas
Corypha australis	s†Trichomanes
†Rœllia ciliata	

All those marked with an asterisk (*) will require extra care, and very careful cultivation, and will not succeed more than moderately well even with this, where the air is very bad. On the contrary, those marked † need only ordinary care, being vigorous and robust. The letter s denotes that the plant requires shade from hot sun at all times.

Planting the Case.—In planting the case plenty of drainage must be used at the bottom, over that a layer of Moss, and then put in the soil. A very good compost that will grow Ferns, Palms, Begonias, and most of the plants mentioned may be made by mixing together about equal parts of loam, leaf-mould, and peat, with a fourth part of silver-sand, and crocks or bricks broken up very small in equal portions. It is far more effective in planting a case, especially if of any considerable size, to arrange it more in the style of a rockery, that is, by piling and fitting together in a graceful and natural manner some pieces of roughish stone, to form a picturesquely rugged mass of porous materials in the bottom of the case in such a manner as to leave a number of holes or fissures at convenient points, which may be filled with soil, and the plants selected placed in these. When planted give a good watering, always using tepid water. With care in watering, aëration, &c., for the future, the case will last for years. In time, however, if they live and do well, some of the plants mentioned, such as Palms, &c., though only the dwarfish kinds are enumerated, will attain such a size as to be inconvenient; they should then be removed and replaced with small plants.

Heating, &c.—Of course where greenhouse Ferns, or indeed any of the plants given in the preceding list, are grown, either some means of heating the case must be resorted to in winter, or the plants must be altogether removed to some place where they can receive the requisite amount of heat, though in the summer nearly all those named will do well without any artificial heat, that is, from the 1st of June till the 1st of October. Many handy little apparatuses for heating such cases can now be purchased, and almost any simple arrangement of hot-water pipes, heated by a suitable lamp, or burner, or boiler, would give the desired result. But the heat, though small in quantity, must be constant and regular, or it will be as bad or worse than none. In a large structure like a greenhouse it does not much matter if the fire goes out for a few hours, even in severe weather, as the quantity of water in the pipes, the mass of brickwork, and the contents of the house all maintain the heat for a long time. Where the contents and all surroundings, however, are on such a small scale, it becomes a very different matter, and if the supply of heat be interrupted even for an hour in severe weather serious results will accrue. Yet only a very small amount of heat is needed, and we think that about the best arrangement is a couple of coils of strong tin or copper pipe, 1-in. or 1½-in. in diameter, running round the sides of the case, with the usual appurtenances of air-pipe, tank, &c., on a suitable scale, a boiler holding two or three quarts, or perhaps more for a large affair, and a good paraffin lamp and burner, properly arranged, and constructed to burn eight or ten hours without attention. Even with such an apparatus, however, great care is requisite, especially in the matter of watering; and in actual frost, if the glass is in direct contact with the outer air, and any of the plants within either touch it or approach within two or three inches of it they are very liable, in fact almost

sure, to be injured, so that some protection or covering becomes necessary. Nothing is better than an old soft blanket or rug, or any kind of cloth, if thick enough, would serve the purpose, and it should be spread well over the outside of the case at night, and in the daytime too if the frost holds. A thermometer should be employed, and the temperature should range from 55° to 65° during the winter for most of the subjects mentioned. The heat should be greatest in the daytime, especially on a bright day when the sun is shining, and least at night. If it drops to 50° at night no harm will be done, but it must not be more than a degree or two less than this at any time, and 70° or 75° for a short time at midday in sunshine will be beneficial.

Unheated Cases.—Where the case cannot be heated in any way, and there is no convenience for keeping the plants elsewhere during the winter (if there is, it is better to grow as many of the things in pots as may be, so that they may be removed to their winter quarters without being disturbed), the only alternative is to fall back upon hardy plants. There are many of these suitable, and almost any plant that is found flourishing in damp shady woods or lanes, or near a waterfall or stream, will do well in a case.

Hardy Plants for Case.—Ferns and Mosses should form the principal subjects, and of the former the following will be found the most suitable for a case, especially if small.

*Adiantum Capillus-veneris (Maiden-hair).
Asplenium adiantum nigrum (black Maiden-hair)
,, Trichomanes
,, marinum (Sea Spleenwort)
Athyrium Filix-fœmina (Lady Fern)
*Blechnum spicant (common Hard Fern)
Ceterach officinarum (Scale Fern)
*Cystopteris fragilis (Brittle Bladder Fern)
Hymenophyllum tunbridgense (Filmy Fern)
Lastrea æmula montana (Buckler Fern)
*Polypodium dryopteris (Oak Fern)
,, phegopteris (Beech Fern)
,, vulgare (common Polypody)
*Polystichum aculeatum and angulare (Prickly Shield Ferns)
Scolopendrium vulgare (Heart's-tongue Fern) var. crispum multifidum
*Trichomanes radicans (Brittle Fern).

Those marked * will need very careful cultivation to do well. Other kinds of Ferns, such as the common Male Fern, Lastrea Filix-mas, the Osmunda, and other large growing kinds may be used in a small state, or in a large and tall case, but in the majority of cases they are unsuitable from their great size. The lovely New Zealand Fern Todea superba has been proved to be hardy under glass, and a plant or two may be tried, but care must be taken to procure one that has been used to cold treatment, and very great care will be requisite in cultivation. This, however, will be amply repaid if the Fern does well. A plant or two of small-leaved Ivy does well in a case—at least in winter, and is a great relief to the monotony of Ferns; the common ground Ivy is as good an one as can be had for such a place, though some of the silver variegated kinds are very handsome. The almost endless varieties of Mosses to be found in our English lanes and woods are another valuable resource; some of the Lycopodiums or Club Mosses are really handsome and effective. Several of the Equisetums, or Water Horse-tails, are effective and easily grown. Three of the most suitable kinds are E. palustre (the Marsh Horse-tail), E. pratense (the Shade Horse-tail), and E. sylvaticum (the Wood ditto). The lovely little Sundew, too, or Drosera, that is so common on marshy heaths in Surrey and other counties, forms a very interesting subject; so does the flowering Buck Bean; and, in fact, almost any of the numberless plants and flowers that are to be found, and evidently luxuriate, in moist and shady situations, will be suitable for the town window case, and an expedition into some part of the country where these situations abound will be amply repaid.

We have sometimes seen the case so arranged by having the tray at the bottom made somewhat deep so that a foot or so of water could be introduced, and so form a kind of aquarium combined. Rough stones or rocks were built up at the sides or ends till above the surface of the water; in these and amongst them interstices were provided, which were filled with suitable soil, and plants, Ferns, &c., placed in these; while a few gold fish, or even sticklebacks, and water plants in their natural element below the graceful arching leaves and fronds above, made a most charming picture. All this can be done in any London window, though not without trouble, and a good deal of it, too, in the first arrangement, as well as some expense; but when once done, and done well, it will last in beauty for years with proper attention and management.

In summer, if the window is at all sunny, some shade must be provided for nearly all the subjects mentioned. Some light material, such as calico, is suitable, and it should be arranged on a roller, so as to be easily brought into use, and be drawn up again when required.

The annexed woodcut represents a Fern case designed by Mr. Williams, of Holloway, for his "Select Ferns and Lycopods."

B. C. R.

HOW TO GROW GLADIOLI.

In choosing a position for Gladioli when spikes for exhibition are required, it is of the utmost importance that an open situation should be selected. There can be no doubt that a deep loamy soil, not too heavy in texture, is the most suitable for the production of spikes for exhibition; but by deep digging and liberal manuring, very satisfactory results may be obtained in soils of even an uncongenial character. Early in autumn the soil should be dressed liberally

Gladiolus Brenchleyensis.

with manure from an old hotbed. After it is spread regularly over the surface, trench the soil up to a depth of 2 ft., and leave the surface as rough as possible, so as to expose a large body of it to the direct action of the frost and rains during the winter; this is of importance in the case of heavy soils, for it is very desirable that they should be thoroughly pulverised by the action of the weather. If this is done it will be in good condition for working in spring, and a pricking over with the fork will suffice to reduce it to a fine tilth, and even in wet seasons admit of the bulbs being planted without unnecessary delay. The planting of the bulbs should commence in March, and be continued at intervals of a fortnight until June. By this means a succession of bloom will be obtained from the earliest moment at which the show varieties may be had in flower until quite the end of the season. If planted in beds the rows should be 18 in. apart, and the beds must be 4 ft. in width. Beds of this size will admit of one row being planted down the centre, and a row on each side at a distance of 6 in. from the edge of the bed. As soon as the plants have made sufficient progress to require support, stout stakes should be put to them. The top of the stake must not be higher than the first bloom, and the stem should have one tie only, and that a strong one of bast. After they are staked the surface of the bed should be covered to a uniform depth of 4 in. or 6 in. with partly-decayed manure. This dressing is of the greatest value, for it materially assists in keeping the soil cool and moist about the roots during hot weather. As soon as the plants show bloom, liquid manure in some form is most beneficial in promoting a full development of the flowers. If for exhibition, the spikes should be cut when about two-thirds of the bloom are expanded, as the lower flowers are generally of a finer quality than those towards the top. In growing Gladioli for garden decoration it is simply necessary to select positions where they will present the most effective appearance, and there prepare the soil for them. They have a fine appearance planted in clumps between Dahlias, Hollyhocks, Phloxes, Roses, and other subjects of a somewhat similar character. They are also very effective planted in clumps alternately with Tritomas, and also associated with large masses of Cannas. They are likewise in every way suitable for intermixing with American plants, the dark foliage of which shows off the richly-coloured flowers to good advantage. The positions for them should be marked out in the course of the autumn or winter, and two or three spadefuls of manure should be dug into them. As a rule, the space for each clump of bulbs should be 18 in. in diameter, and the soil should be turned up to a depth of 18 in. or 24 in. March and April are the best months in which to plant for garden decoration, as they are then at their best during August and the early part of September. Plant from three to six bulbs in each clump, and confine each group to a separate colour. They must be staked in much the same manner as those intended for exhibition, to prevent the wind from injuring them.

SOWING HARDY ANNUALS.

We should not counsel the sowing of hardy annuals in frames at the present time. The season has now arrived when they may be committed to the open ground with the best prospect of success. The thing to do now is to well prepare the soil for their reception. Annuals like a free, deeply-stirred, well-enriched soil. When growing in poverty-struck ground they never truly represent their true worth, for the blooms lack quality, and are not so profusely and continuously produced as when accorded the conditions most favourable to a vigorous healthy existence. Hardy annuals pass the early stages of their existence in a comparatively cool and moisture-laden atmosphere; but just when the greatest strain on their energies is experienced, the weather is apt to be of an extremely trying nature, and, unless there is an unlimited store of food at the disposal of the roots, plants, which up to that time were the hope and pride of the owner, collapse in a most disastrous manner. Choose a dry time, and turn up the beds or border roughly, allowing the soil to lay thus and sweeten; then, breaking the lumps well, add a goodly portion of well-rotted manure, thoroughly incorporating it with the soil, which I may add cannot be too much worked and stirred with the four-tined fork. About the end of the first week in March is the best time for sowing, but should the weather prove inclement, and the earth be in a very weak state, by all means defer it until a favourable change is experienced.

The old adage, "more haste less speed," will apply to the sowing of seeds as to other things, for no time is gained and results are never good when seed is committed to the soil during a period of rainy weather. Generally speaking, the month of March is favourable to seed sowing operations, as drying winds, accompanied, perhaps, by a glimpse of sun, bring the surface soil into that mellow state which the experienced grower so well knows is essential to perfect germination. Wait, therefore, until such favourable conditions present themselves, and having made the surface quite firm, draw a shallow drill, sow the seeds therein, and cover them with about their own thickness of fine, sandy mould. If the plants come up thickly, thin out at once to about 3 in. apart, and before they can in any way crowd each other thin once more, leaving them this time quite 6 in. apart. A hardy, early sown annual will require quite that much space for lateral development, and

cannot fully display its true characteristics unless allowed it. Great resolution is required in thinning out the plant, and few amateurs are found courageous enough to at once afford the necessary space, but allow the young plants to crowd and weaken each other, when it is too late to adopt any remedial measures.

To obtain a due succession of bloom, sowing should be made about every ten or fourteen days, until the middle of May, soaking the drills when the weather is hot before sowing the seed. Hardy annuals may also be sown in the autumn to stand over the winter in the open ground, when they will give a fine display at a time when there is a comparative scarcity of bloom out-of-doors. A free, open spot should be selected about the beginning of September, and the various kinds should be sown in rows quite 6 in. apart, thinning out to 3 in. apart when up, as the object is to endow them with as much vigour of constitution as possible, which can only be well accomplished by exposing them to the full influence of light and air until the power of the sun ceases to make itself felt. About the middle of October transplant them to their permanent quarters, allowing 9 in. from plant to plant. Hardy annuals may also be employed to brighten up the greenhouse or dwelling early in the year. For this purpose let them be sown in pots about the first week in September, leaving one or two good seedlings in a 4½-in. pot and three in a 6-in. pot. Winter them in a cold frame, giving plenty of air on all favourable occasions. Twelve good varieties consist of Godetia Lady Albemarle, Nemophila, Collinsia bicolor, Clarkia pulchella, Leptosiphon aureus and roseus, Saponaria calabrica, Coreopsis aristosa, Collinsia grandiflora, Eutaca viscida, Linum grandiflorum, and Limnanthes Douglasi.

Bulbs after Flowering.—What to do with Dutch and other bulbs after they have flowered in pots appears with many to be a difficult question. My own way of dealing with them is to plant them out where they can be left undisturbed. But the question may arise, where is such a spot to be found? for beds and the majority of borders in which bedding plants are grown require deep winter cultivation. In spring gardening bulbs form an important feature, but they must either be imported or selected ones of home growth, as, on account of their having often to be lifted when in full growth and laid in by the heels, as it is called, to ripen in out-of-the-way places, they diminish rather than increase in size and strength. It is, however, quite another matter when they can have a permanent position, in which they are allowed to perfect their foliage and ripen their bulbs undisturbed in the ground. Taking them up and storing them is an unnatural system—a trying ordeal through which they may live, but that is rather a proof of their strong vitality than that they are in any way benefited by the exposure to which they are subjected. Since herbaceous and mixed borders proper have, however, once more become a reality, positions for bulbs will be found in them; indeed, we have annually planted the remnant of our forced bulbs of all kinds in such borders, and certainly they are capable of taking care of themselves as any plants with which I am acquainted, for they not only grow and flower freely, but increase into large masses, a condition in which they have a far better effect than if planted in rows with geometrical precision. Having stocked all such available positions and the margins of permanent beds devoted to Rhododendrons and similar plants, we last year planted all our surplus bulbs on the edges of our Rose beds and banks, and they are now showing an abundance of sturdy spikes of bloom, which materially add to the appearance of the beds without the least probability of detracting from the success of the Roses, as by the time their leaves get thick the bulbs will be going to rest under their shade, while the same cultivation suits both, merely keeping the soil free from weeds and adding a good top-dressing of rotten manure and rich mould, for neither likes the spade among their roots. It has been remarked that bulbs are difficult to suit as regards soil, but if it be rendered friable enough by cultivation for ordinary border plants, there need be no fear on this score. Of course if the object be to get fine bulbs for any particular purpose, rich soil and plenty of room for each bulb will yield proportionally rapid and satisfactory results; but for affording a brilliant display in the open air, plant well at first, and they will then need but comparatively slight attention afterwards.—J. G.

Thorn Apples (Daturas). — These are annual plants, and very beautiful when well grown. Their culture offers no special difficulty. Fresh seeds are readily raised in an ordinary hotbed, and the young plants should be pricked out singly in pots while small, and finally planted out in the open border. They need ample space for their full development, and should be grown in light sandy soils in preference to such as are of a heavier nature. There are five or six kinds possessing some claim to notice, but those which more especially merit the attention of the amateur are the D. ceratocaula, the D. Metel, D. Knighti, and the D. fastuosa, with its double varieties. The flowers

Knight's Thorn Apple (Datura Knighti).

of most of the species expand towards the close of the afternoon, and close the following morning.

Dwarf Snapdragons.—Last spring I had a collection of Tom Thumb Antirrhinums in eight different colours, and very dwarf, distinct, and beautiful they were. Some of the flowers were striped, others blotched in various forms and colours; but all were good, and, as a rule, the distinct colours were fairly true, which is more than can be said of all packets of seeds marked distinct. Everybody who saw the blossoms admired them, and towards the autumn, when nearly all other outdoor plants were shorn of their beauty, the Antirrhinums seemed to improve, and continued flowering till the end of November. Seeds sown during the next fortnight or three weeks in a gentle heat, when large enough pricked off into boxes, brought on for a time in a close, cool frame, afterwards hardened off and planted out in May, will come into bloom by the end of June, and continue flowering till late in autumn. Here and there one may be found that will grow rather taller than the rest, but these can easily be picked out when the plants are taken from the boxes, as by that time they will have developed their true character. If planted about 6 in. apart, an effective bed will be the result, and a new and pleasing feature may be given to it by planting seedling plants of Acacia lophantha from 2 ft. to 3 ft. apart amongst the Antirrhinums; and if a broad band or verge of the variegated Mesembryanthemum be added, it will impart a neat finish to the whole. With beds of this character there is not much labour or care required, and they continue to improve till long after the usual bedding plants are fit for removal. The Acacia is very elegant, and takes off the flatness of the dwarfer plants, and the light and shade that seem to play amongst its light, feathery branches bring out and improve the effect of the Antirrhinums. If the Acacias be sown now, and brought on in a moderate heat, they will be large enough to plant out by the usual time, but no time should be lost. The Antirrhinums, being hardy plants, may of course be sown in the open air, but if so, they will not come into flower till late in the year, and will consequently not be so useful this season as if sown in the manner above described, in order to have them in bloom from early in summer till late in autumn.—H.

THE COMING WEEK'S WORK

Extracts from a Garden Diary.

Feb. 28.—Potting Gazanias, Chrysanthemums for bedding, and various kinds of Verbenas. Shifting Daphnes, Chorozemas, and Camellias into larger pots, using a compost of loam, peat, sand, leaf-soil, and cow manure for the latter. Potting off young Egg-plants, and re-potting Eriostemons in loam three parts, sand and peat one part; also Epacrises and Heaths. Sowing more Sweet Peas, Mignonette, and Radishes; also Parsnips and Musselburgh and Ayton Castle Leeks. Planting out Globe Artichokes and Potato Onions. Putting in cuttings of variegated Pelargoniums, Begonia parviflora, and Plumbago; also inserting cuttings of Tree Carnations on hotbed. Digging land for crop of Carrots and Turnips. Manuring and levelling Celery land for Strawberries. Protecting Plums with nets. Cutting down plants of Erica hyemalis. Pruning Hybrid Perpetual Roses.

March 1.—Potting Crystal Palace Scarlet Nasturtiums, scarlet Lobelias; re-tubbing Jasminums and Passifloras; also potting large Clematises and shifting into conservatory. Dividing and potting Musk; potting young Fuchsias and Coleus. Sowing Scarlet Gem Melons. Planting Jerusalem Artichokes, and preparing to plant Potatoes close to Peach wall; also planting out remainder of autumn-sown Cabbages. Putting in cuttings of Achyranthes, Salvias, and Senecio. Earthing-up autumn-planted Cucumbers. Putting Dahlias into heat, and Lilacs into Peach-houses for forcing. Digging land for main crop of Carrots and second crop of Broad Beans. Clipping Privet and Holly hedges.

March 2.—Potting dwarf Roses, old and young Fuchsias; also Myosotis, a few more Calceolarias, and all Dahlias that are struck. Shaking out and re-potting standard Heliotropes, and placing them in heat. Sowing Perilla. Putting out Cucumber plants, planting Seakale thongs that are sprouted, and Potatoes under the protection of a Peach wall; likewise a few more Bath Cos Lettuce. Pricking off Borage. Putting in cuttings of Euphorbia jacquiniæflora. Manuring border for seed-beds. Putting a little straw round Rhubarb roots that have started to ward off frost.

March 3.—Potting Azaleas and Agathæa cœlestis. Sowing Godetia, Clarkia, Collinsia, Eucnide, Calliopsis, Zinnia, Alonsoa, Dianthus, scarlet Stocks, and Eschscholtzia in pots, and placing them in cold Vinery; also James's Keeping and Strasburg Onions, Leeks, Sandringham White and Ivery's Pink Celery, Early Horn Carrots, and Early Dutch Turnip, likewise a bed of Radishes under the protection of a wall. Planting Laurels, Roses, Violets, Early Potatoes on south border, and transplanting Cauliflower from pots to hand-lights. Putting strings over young Peas to frighten away sparrows. Cleaning Asparagus beds. Painting late Vines.

March 4.—Potting Palms and Panicums, and also Azaleas that have done blooming, and old Verbenas. Potting off Alyssum. Shifting old Fuchsias that were shaken out a month ago into larger pots. Planting Cypresses, Hollies, and other shrubs, and finishing planting all early borders of Potatoes; and getting in main crop of Potatoes; also remaining Horse-radish, Sage, and Thyme. Putting in roots of Asparagus for succession, and introducing into heat more scented Verbenas, Lilacs, Ghent Azaleas, Roses, Dielytras, Deutzias, &c., for conservatory decoration. Pruning standard and other Roses. Forking in manure among Artichokes. Sowing Victoria Stocks, Balsams, and Cockscombs in pots.

March 5.—Potting Vesuvius and Christine Pelargoniums and yellow Calceolarias for flowering in pots. Potting off Chrysanthemums, boxing off Salvia fulgens, and shifting Tree Carnations. Sowing Virginia Stocks, Clintonias, Godetias, and more Turnips and Early Horn Carrots on Peach border; likewise sowing pickling and other Onions, Leeks, and Parsley. Earthing up remainder of Seakale crowns intended for blanching. Clipping Box edgings and finishing cutting Grass edgings. Digging border ready for Gladioli. Stopping Vine shoots that are sufficiently forward for that purpose. Putting pot Vines in warm Vinery, and some little Azaleas into a cool house to retard their blooming. Putting flower-pots over Seakale crowns, and covering them over with soil. Filling Cucumber-pit with fermenting material ready for planting with spring-sown plants.

Glasshouses.

Chrysanthemum cuttings struck at the end of the year will by this time be well rooted and hardened off; they should be at once moved into 6-in. pots, using ordinary loam made rich with one-third rotten manure and leaf-mould in equal proportions, to which a little sand has been added. There is no grosser-feeding plant in cultivation than the Chrysanthemum; to grow it successfully the soil must be rich, and in its early stages it must never be allowed to become pot-bound, for if this occur, no after treatment will ever impart to the plants their wonted vigour, as the stunted condition the roots get into when confined in little pots has the effect of prematurely hardening the shoots. It will be necessary to decide upon the desired shape of the plants; in most cases it is advisable to adopt two or three forms, but the flat, Mushroom-headed fashion should never be followed. The most generally useful for decorative purposes are plants with a dozen or more shoots, ultimately trained with just as many sticks as will support them. All plants intended to be grown thus should, at the time of potting, have the points pinched out to induce them to break several shoots; this shape will be found the most suitable for the medium-sized, freest-flowering of the large varieties, and also for the Pompones. Many of the large kinds that pro-

duce the finest individual blooms, are not capable of being seen in their best form if many flowers be allowed each plant; for ordinary purposes, six or eight will be enough on each; for growing in this way, the plants must be also stopped now to cause them to form three or four shoots. Amateurs who are disposed to attempt the production of a few of the finest flowers, may do so by only allowing each plant in a 9-in. or 10-in. pot to carry from one to three flowers; these will be found very effective when in bloom if arranged in the greenhouse amongst the dwarfer growers, relieving the even surface, which is justly held objectionable in a stage filled with Chrysanthemums of nearly the same height. To grow them in this way the young plants now potted should not be stopped at all, but simply trained to a single stem all through the season, allowing it to branch out in the summer near the top to as many shoots as it is destined to carry flowers. Chrysanthemums are frequently seen but mere shadows of what they are capable of being produced, yet they are easily managed, and well repay a little extra attention.

Cinerarias and Calceolarias.—Cinerarias will now be pushing up their flower-stems, and will be benefited by using altogether liquid manure of a moderate strength; this treatment will be found of greater efficacy to the plants than giving it in a stronger state alternatively with clear water. If some of these late-sown Cinerarias be removed to a frame placed where it will not be directly under the influence of the sun, the supply of these useful flowers will be considerably prolonged; all the protection they will now require can be given, should a little frost occur, by shaking some litter round the sides of the frame, and covering the lights with a couple of mats. Herbaceous Calceolarias, that have now filled their pots with roots and are pushing up their flower-stems, will have their blooming capabilities much increased by the continuous use of liquid manure; these should be in a warmer place than the Cinerarias, and a vigilant look-out kept to see that aphides do not get established upon either of them.

Pelargoniums.—The earliest-blooming, large-flowered, and fancy Pelargoniums will now be showing their flowers, and as the roots by this time will have taken full possession of the soil, they should be supplied with manure water once or twice a week; if attention in this matter be not paid to these plants, there is a difficulty in keeping the foliage of that dark green, healthy hue which so much enhances their appearance when in flower.

Bedding Plants.—Cuttings of Verbenas, Heliotropes, Ageratums, Petunias, Lobelias, and Fuchsias should be taken off and put in to strike as the old plants furnish them of sufficient size; see that they are quite clear from green fly when put in, otherwise they will do little good; should, however, any be found upon them, the best plan is to dip the cuttings in Tobacco-water, washing them in clean water afterwards. Keep on propagating the more tender kinds of bedding subjects, including Alternantheras, Iresines, and Coleuses, until there is not only enough to plant, but a good reserve to fall back upon in case of loss. Dahlias of choice varieties that are intended to be increased by cuttings should now be put in a slight heat; if the roots be placed in a broad shallow box, with a little soil about them, they can be set near the front lights in a Vinery that happens to be at work, which is much better than the usual practice of putting them on the floor of the Vinery, from which position they are likely to get drawn up weakly; such a house as the above not being available, a frame on a slight hotbed will be found ample for the purpose. Tricolor Pelargoniums, being so much slower in their growth than the ordinary green-leaved kinds, should, if possible, be kept warmer than the latter, so as to get them up in size before planting out time, for if not sufficiently large when turned out, the little progress they make causes the season to be half over before they produce the desired display; 50° at night will not be too much for them. The above treatment will answer either for plants struck last summer or for such as were taken out of the beds, cut back, and potted in the autumn. Some annual Stocks should be sown in small pots, dropping half a dozen seeds into each; these ought to be stood on a slight hotbed, or in a house where there is a little warmth, being careful not to over-water the seeds before vegetating, or the young plants when up until they have acquired some strength, as they are extremely liable to damp, the best preventive of which is to keep them as close to the glass as possible directly they appear above-ground. If well attended to and a little more root-room allotted to them as they require it previous to planting out time, they will flower in advance of later sowings.

Fruit.

Pruning and nailing should now be completed as soon as possible. The principal thing that amateurs ought to observe in carrying out this work is to encourage and retain, as far as possible, over the whole surface of the tree an even amount of bearing wood; this is especially necessary in the case of young trees, which are often spoilt by getting the bearing shoots to the upper and outer portion of the branches; this is generally caused by retaining too many strong branches in the centre of the tree, whereas, if they be kept more open, there is room for a uniform quantity of young bearing shoots that can always be had with sufficient foresight. In shortening a young shoot of last summer's growth near the base or centre of the trees, the operator should always bear in mind that there is a two-fold object in view—the production of fruit for the current year, and the growth of one or two young shoots that will be laid in during the summer for fruiting next year. The point to which he cuts back should, as far as practicable, be regulated by the most suitable position for the present season's growth to occupy. After the tying and nailing is complete, use every means, as recently recommended, to retard the bloom by keeping the sun from it on bright days.

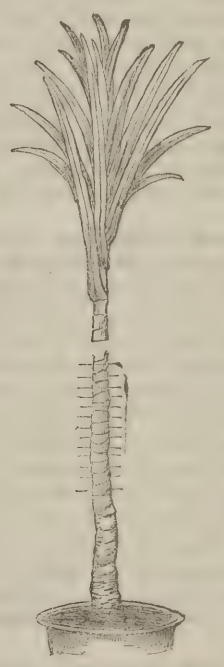
Worms on Lawns.—Correspondents so frequently ask how to destroy worms in lawns, that I am tempted to send my own practice. I dissolved 1 oz. of corrosive sublimate in an imperial quart of hot soft water, and put a small wineglassful of this into a watering-can which contains about 2 gals., and watered in mild damp weather, when the worms lie tolerably near the surface. It was at once pleasant and disgusting to see, in less than a minute, the great lob-worms crawl out of their holes. I took them up and threw them into a pan of strong salt and water, to kill them. I then rolled my little lawn, which used each morning to be covered with worm-casts, and there never has been one since. This is two months ago, and I cannot see that the Grass is in the least injured. My only fear is that I have too completely driven away or killed the worms, for of course their holes are very useful in conducting surface water into the drains and keeping the soil open. After two or three weeks the Grass looked as if it had just been rolled; of course all the water I used was rain-water. I found the remedy in a little book called "Garden Receipts." The directions were 1 oz. of corrosive sublimate to 40 gals. of water. I used it rather stronger. Mine is an old garden where worms are extremely plentiful and annoying.—W.

Soot and Lime *v.* Birds—Those who, like myself, are troubled with birds picking the buds off their Gooseberry and Currant trees may derive some benefit from the following remarks: I prune about the beginning of the year; after all are pruned, I have both Gooseberry and Currant bushes well dusted with lime and soot mixed when the bushes are wet, in order that the mixture may adhere to the trees, and the result has been most satisfactory, not a bud having been taken after the bushes were dressed. I have, however, had to repeat the operation lately, as the rains had nearly washed the first dressing off.—W.

Law Relating to Greenhouses.—Mr. F. Norris (page 595) has made incorrect statements on the above subject. The Building Act clearly states in its list of exemption "all greenhouses, so far as regards the necessary woodwork of the sashes, doors, and frames;" and therefore in all other particulars they are not exempted, but are to follow the rules of the Act. Houses for rearing plants for sale, and placed in the midst of a nursery ground, are viewed as chattels in trade, but not so other houses for plants.—Edwin Nash.

GLASSHOUSES AND FRAMES.

How to Propagate Dracænas.—There are two ways of increasing Dracænas—the first (fig. 1) by cutting off the top, which should be put in single pots in equal parts of peat, loam, and sand, well mixed together; give a good watering and plunge the pots up to their rims in a good brisk bottom-heat, keeping them close for two or three weeks, and giving a slight sprinkle of water overhead every morning. They take about two months to get well rooted, when air may be gradually given them, and they may be turned out of the frame. Keep them, however, on a gentle bottom-heat for a week or two, when they can be potted and placed in another part of the plant stove, and will soon make fine plants. By cutting up the stems, as shown in fig. 2, and putting the pieces in well-drained pots or pans, just covering them about ¼ in. with fine soil over the tops, they will soon begin to grow if plunged in a good bottom-heat, and treated in the same manner as the tops. Sometimes they push forth numerous growths according to the strength of



Methods of propagating Dracænas.

the stems; these all root, and each one when cut away will make a plant. The old bottom will push out several shoots, which may also be used for cuttings. Dracænas may be increased all the year round, but the best months are May and June.

Gloxinias from Seed.—"W. W. P." (p. 530) must have been unusually favoured to find that out of "two small packets of seed" he could raise 60 Gloxinias "every one quite distinct." My experience with seed from the best strains is very different, many duplicates being found in every lot raised. The growth, in less than six months, to plants "20 in. across," with flowers of 4 in., will be, I think, even more startling to most growers. Although often a prize-taker with these plants I have never had, nor seen in this part of the country (the western) any such size plants grown in six months as "W. W." P. has been able to do. Has he been unusually successful? or are we behind the times here? Will he tell us the size his bulbs are, and in what he has grown them?—W. B.

Plants for a Small Greenhouse.—There is a wonderful variety of plants that do well in a cold greenhouse. A temperature of from 35° to 40° is excellent for winter purposes, except that in such a temperature it is not possible to have in midwinter other than the hardiest and earliest plants in bloom. Roman Hyacinths, Christmas Roses, Primroses, Camellias, Primula denticulata, &c., will yield the very earliest bloom in such a temperature, and to these will follow Chinese Primulas, Cyclamens, Cinerarias, and herbaceous Calceolarias, all of which will live well in a cool house through the winter, provided frost be excluded,

Genistas, Coronillas, Deutzias, Dielytras, and early Azaleas follow in succession, and furnish an abundance of bloom. For the summer season the best plants are show and zonal Pelargoniums, Fuchsias, Balsams, Begonias, and similar plants, all very gay and easily managed. These will keep the house gay until autumn, when Chrysanthemums, Solanums, &c., might terminate the year. To these an abundance of plants can be added, but the dimensions of a small house are so limited that it would be useless to suggest more, especially for summer decoration, where a Vine in foliage will exclude light and render the cultivation of plants difficult. A quantity of hardy early spring flowers, such as bloom naturally in the open ground in March and April, if lifted into pots and placed in such a house early in winter, will commence to produce bloom much earlier, and prove most valuable for decoration before other and tenderer plants have commenced to flower. A few Roses in pots brought into the house early will bloom a month before those out-of-doors. These can be returned to the open air as soon as the bloom is over. A few tree Carnations in pots will yieid winter bloom, and furnish some fine "buttonholes." Common Auriculas in pots are pretty sn a front stage, and do admirably with Chinese Primulas and Cyclamens. The obtaining of flower all the year round is difficult to accomplish without strong artificial heat, but the plants named above, if properly treated—a matter, be it understood, of the first moment for their welfare—will give a very long season, although the artificial heat be wanting.—D. B. M.

Nicotiana longiflora.—Seeing several enquiries respecting the cultivation of this plant, I beg to give my experience. Last autumn I bought a packet of seed which I sowed in a 6-in. pot in light soil, from which I got over 50 plants. These, when large enough, I transplanted into 4-in. and 5-in. pots, using some old rotted turf with part sand and manure. Some of them bloomed before Christmas, but only slightly, having only 2 and 3 blooms on. I have now over 20 plants, some of them with 4 and 5 flowering stems, each plant having from 12 to 20 leaves, some leaves being over 2 in. wide and 6 in. long. They are grown in a cool greenhouse, as I do not use any artificial heat, only in very severe weather. From what I can see of the plant, it is as easy to grow as a common Geranium, for I have had no trouble at all with it. In a few weeks from now I expect to have scores of blooms.—E. M., *Middlewich.*

Rock Forget-me-not (Omphalodes Luciliæ).—Of the numerous additions which we have had of late years to our lists of hardy flowers perhaps none have been more universally admired than the subject of the accompanying engraving. It belongs to the Borage family, which furnishes us with so many beautiful border flowers. Though its flowers lack the deep azure blue of its pretty congener, the spring-flowering Omphalodes (O. verna), there is something in their pale porcelain-blue tint, which changes to a pinkish hue, that is quite unlike anything which we have amongst hardy flowers, and this, combined with its handsome glaucous foliage and the graceful creeping habit of its slender branches, which throughout the greater part of the spring and summer months bear a copious supply of blossoms, has elevated it to the rank of plants that cultivators like to place in the most select spots in the rock garden. Its perfect hardiness, too, much enhances its desirability. It succeeds well when planted in a border or on a rockery, where its branches hang over the ledges, but the place must be thoroughly drained, for though it requires abundant waterings during the growing season, it is very impatient of stagnant moisture at the roots or about the crowns. Slugs, unhappily, are particularly fond of its foliage; therefore the plants should be guarded against their attacks, and for this purpose strips of perforated zinc about 3 in. wide, and bent so as to form a ring round the plant, will be found to be as effectual as any plan that can be adopted. It may be readily propagated by division or by seeds, which in some seasons it develops freely. It is very successfully grown in Mr. Wheeler's nursery at Warminster.—W. G.

Winter-blooming Deciduous Hardy Shrubs.—The three highly-ornamental and usually most free-flowering hardy shrubs represented in the woodcut on page 623 are not by any means as generally known or as frequently met with as their season of bloom and (in the case of the first-named) delicious fragrance most certainly entitle them to be. Chimonanthus fragrans grandiflorus comes into blossom about Christmas time, and remains in beauty for about a month. Its flowers, besides being of larger size, are also of a much brighter colour than those of the type which is also known to some under the name of Calycanthus præcox, being of a decidedly golden hue, with claret-coloured centre, while its flowers are of a dullish white. The blooms of the ordinary kinds, however, exhale a considerably greater degree of fragrance than these of the brighter coloured and larger-flowered variety, thus apparently making up for their inferiority in size and beauty. The variety now figured is usually much more free and profuse blooming than the common kind; the perfume of these shrubs much resembles that of the common Jonquil. Hamamelis arborea is more generally known, and about three weeks earlier in blooming than the other variety. Its flowers are also considerably larger in size and more conspicuous in appearance, having a deep claret-coloured centre, which is altogether absent in H. Zuccariniana; it comes into bloom about the middle or end of January. Hamamelis Zuccariniana produces a profusion of curious starry blooms of a pure canary-yellow, expanding about the middle of February, and remaining in beauty for about three weeks. It is well worth adding to every collection of hardy ornamenal shrubs, though not so conspicuously ornamental as its better-known relative. A south wall or fence suits these shrubs admirably, and they succeed in any good garden soil, but a sandy loam suits them best.

Rock Forget-me-not (Omphalodes Luciliæ).

ANSWERS TO QUERIES.

4197.—**Climbers for Greenhouse.**—Tacsonia Van Volxemi and exoniensis are fine subjects for covering the roof of a cool greenhouse, as are also any of the cool varieties of the Passion-flower. For a large structure, Bignonia jasminoides is very suitable, as it grows with great rapidity, and affords plenty of shade. Lapageria rosea and alba are two fine climbing plants for covering a roof, but they do not grow quite so rapidly as the first mentioned subjects until they have become well established. Where anything choice is sought for, they should however be preferred, their beautiful wax-like blooms lasting a long time in perfection, and the foliage itself being dense and deep in colour.—C. B.

4198.—**Plants not Flowering.**—We should imagine that you have maintained too high a temperature, and that the air has been at times too arid. Defective root action would, however, account for the roots turning brown. Perhaps you have given too much water. As the pit contains a miscellaneous selection, we would advise that the temperature do not exceed 50° by night, and 60° by day, quite enough in dull weather for Cyclamens, Spiræas, and Salvias. Give a little air in the day-time when the weather is favourable, and water carefully. The great mistake that many make in forcing plants into bloom, is that of maintaining too high a temperature, especially at night during dull weather, and at night, which often has the effect of paralysing the functions of the plants, inducing torpidity of the roots and a general weakening of the tissues.—J. C. B.

4215.—**Failure of Pot Roses.**—We should conclude that the failure is due to the low temperature. The Rose is a hardy plant, but the young growing wood is extremely sensitive to sudden changes, as may be witnessed in the spring, the shoots and flower buds soon becoming disfigured when exposed to the frosts and biting winds. When forced at this early period of the year the wood is naturally very tender, and a sudden fall of the temperature to such a low point would suffice to cause the mischief. The guano water at the strength stated would not have injured them.—C.

4209.—**Hedychium acuminatum.**—This plant thrives best in a temperature of 55° in the winter, and 60° to 65° during the spring months. A compost, consisting of loam, leaf-mould, and peat, in equal portions, best fulfils its requirements, adding enough coarse silver sand to keep it open. Give good drainage, placing a little rough peat on the crocks, for this plant likes plenty of water when growing, but is impatient of stagnant moisture at the roots. Pot firmly, but do not ram the soil in so as to make it hard; merely tapping the pot upon the bench will suffice, making the surface quite firm. March is the proper time for repotting.—J. C. B.

4210.—**India-rubber Plants in Windows.**—The India-rubber is by no means a difficult plant to grow in rooms, but the apartment must be a warm one. It will not thrive in a cool room during the winter, but casts its foliage when thus placed. It is a plant that likes plenty of moisture at the roots when in full growth, but which quickly feels the effects of an over-dose of water in the winter. We should fancy that the plant in question is suffering from torpidity of the roots caused probably by an over-wet state of the soil. From now until finer weather comes allow the mould to dry out and then give just enough to moisten it through. In summer during hot weather give more frequent supplies, and should the plant appear at all pot-bound shift it into the next sized pot. All plants grown in rooms should have the foliage well sponged, both the upper and under surfaces, at least twice a week, as when the pores get choked with dust the leaves are sure to decay.—J. C.

4235.—**Propagating Hoya bella.**—Cuttings of the growing wood may be taken off early in the summer, cutting them to two joints and inserting them in a compost of two-thirds fibrous peat and one-third silver sand. The pots should be filled to quite one-third of their depth with drainage, placing thereon some rough material, and filling quite to the rim of the pot with the compost and making it firm. Water gently and place in a brisk heat under a hand-glass, shading of course from sun, but otherwise admitting as much light as possible. Give a

little air every morning until the cuttings are taken and then inure them gradually to the atmosphere of the house.—B.

4220.—**Gloxinias for Winter.**—If you really wish to have Gloxinias in flower in November, you will have to rely upon seedlings. Gloxinias may be had in bloom from early summer to the beginning of or even far into the winter; but to effect this successional sowings of seed must be made throughout the spring. Old bulbs will soon, even if kept comparatively cool, be showing signs of life, and must be potted up and grown along. They may be potted any time between now and May, and of course the sooner they are encouraged to make free growth the sooner will they bloom. When potted before May they need to be placed in a warm house, and are grateful in their earlier stages of growth for a little bottom heat. After the 1st of May they may be potted and placed in a cool house, keeping them as warm and close as possible, the best way being to cover them with a handlight, as then they get a few degrees more warmth and do not dry out so much. To get plants for winter blooming sow the seed in a brick heat about the beginning of April in sandy peat. Prick them off when large enough into pans, and from thence transfer them to small pots, shifting them on as required, so that by August or September they will be occupying 4½-in. pots. The Gloxinia delights in warmth and moisture, with a tolerably free circulation of air in fine weather. Peat and a little leaf-soil is about the best compost, and although the plants should never know the want of water they should never be heavily moistened.—C.

4236.—**Heating Greenhouses.**—In answer to "Novice" I may state that 4-in. pipes were chosen for economy; that the arrangement is a single flow and return, which runs up one side and along the farther end of the house. On the coldest night of the season, when the thermometer outside stood at 5°, my house was never down to 40°, and during the whole severe period the cost of fuel only reached 1s. 8d. per week. My stove is furnished with a 6-in. iron chimney, 10 ft. high. I have no knowledge of any stove without a chimney, nor do I think such could be used with any fuel but charcoal.—P.

4206.—**Utilising Frames.**—Construct a pit below the ground level the length and width of the frames put together (say, 28 ft. by 6 ft.) and about 18 in. deep. Set the boiler in one end, with the flue running across, chimney at back, and the pipes running right round, if 4-in. pipes once round will be plenty. Set the frames on side by side, and fix in each, at the bottom, a sheet of strong galvanized iron thickly perforated with small holes, held up by two or three bearers. Arrange evaporating pans on the flue and pipes to give a moist atmosphere. In winter, fix a number of boards across the frames, 2 in. or 3 in. above the false bottom, leaving a space, say 1 in. between each, on these bedding plants, and the heat will rise and keep them safely. In summer, take away the boards and cover the false bottom with about 2 in. of spent hops or Cocoa-nut fibre, providing a mound of earth at one end (the back) to plant the Cucumbers in. This will give a good bottom heat, and vines may run along the bottom as in an ordinary frame, thus doing away with the bother of tying up to rafters, &c. Keep the hops or fibre constantly moist. No manure will be needed. The frames should be in a sunny position, facing south; or else run the pipes round inside the frames themselves, (above ground) dispensing with the false bottom. Have moveable boards for plants in winter, and fill up the pit with manure and soil for the Cucumbers, &c., using the pipes to give top heat instead of bottom.

—— Probably the best arrangement you can adopt in heating a range of frames with boiler and pipes will be to fix the boiler under cover at one end, and carry your flow-pipe as high as you can along the back of the frame and the return in front. Long manure may be used to help general bottom heat, by putting a good bed of it inside, but of course the pipes must not be buried. These ought to be up in the frames rather than beneath them. There may be three divisions, say one of three lights and two of two lights each, the one nearest the boiler will be the warmest. You do not require any special heating power if you do not force, and ordinary greenhouse plants will not want forcing in winter, nor Cucumbers in summer, but Melons want plenty of heat.—A. D.

4204.—**Manure for Azaleas and Camellias.**—It all depends. If the plants are large and the pots full of roots suitable manure may be given with advantage when the plants are coming into flower. Weak liquid manure may be given to young plants under similar circumstances, or some concentrated stimulant, such as Standen's Gardeners' Friend, may be used; the quantity must depend upon the size of the plant and pot. Re-pot either at the beginning of the growing season or else when the buds are set; some adopt one time, and some the other. I think the former time is best for young plants.—E. H.

4241.—**Dianthus Heddewigi.**—Eastern Queen, a light ground flower with dark coloured blotches, and Crimson Belle, rich crimson and single flowered, are both capital showy kinds, and make beautiful beds. Masses of suited kinds as obtained from ordinary packets of seed

Group of hardy winter-flowering Shrubs. 1, Chimonanthus grandiflorus; 2, Hamamelis arborea; 3, H. Zuccariniana.

are very charming, the continuity of bloom depending much upon the good quality of the soil. The double diadematus is a superb kind, producing large brilliant coloured flowers. These kinds are 1s. 6d. per packet, but good mixed kinds may be got for 6d. per packet. The best time to sow is early in April and in pans under glass, pricking out the young plants on a warm border till wanted for the beds.—A. D.

4226.—**Plants for Winter.**—I know of no plants that would stand in rooms with gas without injury in winter, but of course with the means your correspondent possesses there should be no difficulty in keeping up a succession of flowering plants. To begin with bulbs, there are Tulips, Hyacinths, Crocus, and Narcissus, Lily of the Valley, Mignonette, Primulas, Cyclamens, Chrysanthemums, tree Carnations, Bouvardias, Epiphyllums, Dendrobium nobile, Cypripedium insigne, Tea Roses, Christmas Roses, Spiræa japonica, Violets, Deutzia gracilis, Dielytra spectabilis, Lilacs, Weigelas, Laurustiuns, Azaleas, Camellias, Heaths, Epacris, Eupatoriums, &c. Ferns and foliage plants would stand the impure atmosphere better. Dracænas, Ficus elastica, Aloes of various kinds, Palms, Grevillea robusta, &c., might be used as background, with flowering plants to give colour and to be frequently renewed.—E. H.

4205.—**Stocks for Exhibition.**—The best summer exhibition stocks, because most dwarf and compact, are the pyramidal section, in which there are a dozen or more kinds, white lilac, creamy yellow, carmine, red, purple, crimson, and several others. These grow to a height of about 10 in., have a massive centre niche and three or four large side ones. They all flower at the same time, and should be sown under glass without heat in April, say about the end of the month for you to have them good in August. If sown in March they bloom in July. Sow the seeds in pans thinly, expose the young plants for a week in the open air before planting, then lift them carefully and dibble out in rich soil about 12 in. apart.

4230.—**Climbers for Walls.**—We should advise the planting of the Passiflora on the sunniest wall and the Rose where there is partial shade; there its blooming may be prolonged. You cannot get better Tea Roses than Gloire de Dijon, creamy-buff; or if you prefer a white one get Marie Guillot; and if a deep coloured one, then have Cheshunt Hybrid; all are strong growing. Passiflora cœrulea is one of the hardiest of the family, and thrives well in ordinary good garden soil. The Roses do best if the ground be deeply moved and well manured. Plant both about the middle of March, getting strong plants in pots, but on turning out see that the roots are laid out, and not left in a ball. Nail the strongest shoots to the wall as soon as planted. But little pruning will be needed for the first season.—A. D.

4231.—**Poultry Manure.**—Poultry manure may be used for any crops, but should not be applied in its fresh crude state. We prefer spreading it over the fallow soil during winter, and permitting it to get well washed in prior to being dug in. It is well also to mix it with decayed garden refuse or leaf-soil for a few weeks before adding to the soil. It is most unfit to use or mix with hotbed manure, as it emits no heat and absorbs the heat emitted by the stable manure in process of decomposition. In the same way Cabbage stumps would be of no use added to a hotbed, but if first laid on the ground neatly and compactly to make a base for the bed they would do good service.

4207.—**Propagating Clematis.**—In the nursery trade Clematises are propagated by means of layers and by grafting. The former is done by pegging down and tonguing the wood at the bud joints, and these, throwing roots during the season, make plants. Others are worked upon stocks of common kinds that propagate freely, or upon pieces of roots. These stocks can no doubt be obtained from Mr. Noble, Bagshot, Mr. Jackson, of Woking, or Mr. Cripps, of Tunbridge Wells, each of these being large growers. We know nothing as to price, but that can be ascertained on application as above.

4213.—**Border for Pansies.**—Any shaded or partly shaded border will suit Pansies well; but the plants will draw somewhat where light is excluded. A warm border suits the Pansy in the winter, but the heat fairly burns up the plants in the summer. The soil should be worked deeply, and have a good dressing of rotten manure, well forked in before planting; a top dressing of leaf soil, or similar light material, that will at once enrich the soil, and keep it open, will do much good. The best plants are those obtained either from cuttings or rooted pieces, and turned out with balls of roots or from pots. These may be planted early next month, and encouraged to make strong growth to secure fine blooms.—A. D.

4156.—**Vegetables in Shaded Places**—Some Radishes may be sown early under Apple trees, and early Lettuces may also be had; also early Kidney Potatoes may be grown to be lifted early in July. Dwarf Broad Beans, such as the Dwarf Green Gem, and Dwarf French Beans may also be sown thinly and a fair crop obtained. Jerusalem Artichokes will also grow. Then in winter, Sprouting Broccoli will give a fair crop, and some of the Kales, such as the Scotch and Cottager's may do. Many kinds of hardy plants, such as Primroses, Polyanthus's, Daisies, Pinks, Wallflowers, Violets, and similar things will do well beneath trees. Perhaps the most suitable under-crop is bush fruit, such as Currants and Gooseberries, as their fruit is gathered before the Apples are ready, and the treading of the soil does not affect their welfare.

4157.—**Potatoes for Clayey Soil.**—On a cold wet clay soil plant nearly on the surface in shallow drills, and fork soil over the rows to bury the sets; also fork up between the rows before earthing to keep the soil light and dry on the surface. Good early kinds are the Ashleaf Kidney and Beauty of Hebron, an improved early Rose, and for late crops Magnum Bonum, King of Potatoes, Victoria, and Grampian, all good cropping and table kinds. The advantages of allowing the seed-tubers to sprout before planting are these—first, you are assured that the sets will grow; second, you save perhaps ten days or a fortnight, or in cold soil may plant that time later with benefit, and if you want to do so you may thin out the growing shoots. When this is done there is a smaller number of tubers, but these are finer. It is a good plan to thin out these shoots when tubers are specially wanted for exhibition.—A. D.

4182.—**Cleaning a Paraffin Cask.**—Put an armful of shavings into the cask and set them on fire, let it burn about twenty minutes or until you find the paraffin is consumed, then turn the cask over to put it out. This must be done in an open place, as it makes a great flare for a time. When the fire is out cleanse the cask with water and washing soda; this will render it perfectly sweet for rain-water or other use.—W. J. C.

4138.—**Treatment of Pelargoniums.**—If your plants are several together in the same pot, they should be potted separately in small pots, the best time for doing so being the middle of March. The compost should consist of two-thirds loam and one-third leaf mould, adding to it a little coarse silver sand. When the soil is seen to be full of roots shift them into 3-in. pots, and later on into the next size receptacle. Be careful not to water heavily after each shift; keep the soil moist, but do not at any time give enough water to bring it into a clogged, sour, pasty condition. By the beginning of August each plant should be well established in 4½-in. pots, and will flower freely. Towards the end of the summer they may appear to need nutriment, which may be given them in the form of a top dressing of some concentrated manure, and when the tops are full of roots and the weather is hot and dry, give plenty of water at the roots. During March, April, and May encourage growth by maintaining a warm atmosphere, sprinkling them overhead on hot days, and ventilating freely in mild weather. By the latter end of May and all through the summer free ventilation night and day must be given, or the plants will run too much to foliage, and will give but little bloom. If grown in windows the best plan is to place them in the open air after the beginning of June. Geraniums require heat, air, and strong light to perfect their tissues and bring them into a flower-bearing state.—C.

—— Stop them by pinching out their ends, which will induce them to throw side shoots. In a fortnight after stopping re-pot them into 6-in. or 7-in. pots, using a compost of three parts turfy loam, half a part thoroughly decomposed cow dung, one part peat, and half a part silver sand, well mixed, and with good drainage. Plenty of fresh air and light are required for their well-being; a close atmosphere is injurious; do not give more water than is absolutely necessary. Train out the shoots as they grow to small sticks, keeping them hidden as much as possible, and, keeping the plants thus trained, you admit light and a free circulation of air to the interior of the plants, and get rid of yellow leaves which we often see in plants whose foliage is kept cramped together. With careful attention the plants thus treated will come into bloom in the beginning of July. When the pots are filled with roots weak liquid manure may be given.—W. L., *Cheltenham*.

—— If "F. C." will refer to last week's GARDENING ILLUSTRATED (No. 99) there is mentioned by "W. W." an Onion Trebons attaining the dimension of 12 in. or 14 in. under ordinary treatment, and in every way answering to the description of that required. Last year in consequence of the previous wet summer, many seeds sold even by the best firms failed to germinate, but if the seeds were good, the failure no doubt was caused by sowing too deeply. The ground for Onions should be deeply dug and well manured, then rolled to make firm, and seed sown in drills about the end of February, not more than 1 in. deep, and about 9 in. between the rows. Tread them down well after planting; when large enough thin to about 4 in. apart. The finest bulbs, however, can be obtained by sowing in the autumn, say the end of August, and transplant early in February, taking great care not to injure the roots, by removing each plant with a ball of earth adhering.—J. V. A.

4174.—**White Squills.**—We should think that Scilla campanulata major alba and patula alba would meet your requirements We believe that they may be obtained at any of the hardy plant nurseries near London.—C.

4176.—**Snails on Ferns.**—Lay some Cabbage or Lettuce leaves round the pots, and in amongst the foliage, and examine them about 10 o'clock at night. You will catch them all off in the course of a few days in this manner.—J. C. B.

4183.—**Liquid Manure.**—The drainings from a pig-stye may certainly be used for pot plants, such as Geraniums, Fuchsias, and other soft-wooded subjects, but not for Azaleas, Heaths, &c. About half-a-pint to two gallons of water would be a safe mixture. It is better to administer liquid manure weak and often than to give strong doses, which often do more harm than good.—C. B.

4184.—**Potatoes for Seed.**—The tubers will do very well for planting. Lay them out in a dry, light, cool, airy place, and they will then form short spurs, and will be in good order for planting when the time arrives.—J.

4232.—**How to Destroy Worms in Lawns.**—There is no doubt that paraffin oil will kill worms or any other living thing if it reaches them in a right proportion. Put ½ oz. in a gallon of water, and keep it well mixed during the application of it by constant agitation.—E. H.

4224.—**Tacsonia Van Volxemi.**—I don't think 6° of frost for a few hours only would kill the Tacsonia, but if the temperature continued so low for any length of time it would kill it, as the soil and roots would become frozen. Examine the roots.—E. H.

4202.—**Scale on Peach Trees.**—Dissolve 8 oz. of Gishurst compound in a gallon of soft water, add half a wineglassful of paraffin oil, and thicken with clay to the consistency of paint; apply with a brush carefully on the young branches where the buds are; the older wood may have it well brushed in. It should be done at once before the buds become too prominent.—E. H.

4222.—**Newly-made Kitchen Garden.**—Your garden should be in good condition for most plants without more manure. A further dressing for Onions might not be amiss, and the same remark applies to Celery.—E. H.

4201.—**Growing Tomatoes.**—Tomatoes may be grown and fruited in any sized pots from 8 in. upwards. Of course the larger the pot the stronger the plants will grow. If large pots are used, train the plants on the roof; if small ones, train them to stakes and keep the side shoots well pinched back. Plant them in turfy loam well enriched with manure, and leave space on the top of the pots to add a top-dressing when required.—E. H.

4221.—**Shrubs for Shelter.**—There is nothing so good as the common English Yew, and they grow fast when well established. Have the ground well trenched and prepared, and procure strong plants that have been frequently transplanted.—E. H.

4223.—**Spiræas not Flowering.**—The Spiræas should have been divided and planted out for a couple of seasons. They will not go on flowering perpetually in pots without some recuperative treatment. Divide now and plant out till they become strong patches, then pot again. A strong root may be made into three or four.—E. H.

4203.—**Cutting Down Laurels.**—Do not cut down the shrubs before March. It will be more easily to distinguish where life remains then than now.—E. H.

4225.—**Strawberry Plantations.**—No; only to keep the surface stirred with a hoe. Mulch with long littery manure when the blossoms begin to open to keep in the moisture and the fruit clean.—E. H.

4228.—**Buds Falling off Geraniums.**—It is difficult to say what causes the buds to fall off Geraniums without knowing their condition and treatment. Gas would make the buds to fall; so would too much or too little water applied to the roots, or if there are worms in the pots and the drainage imperfect; cold draughts of air will cause buds to fall; in short, checks of any kind will do it.—E. H.

4229.—**Branching Larkspurs.**—The branching Larkspur may be sown early in March if the soil is light and warm, but I should recommend a further sowing to be made about the end of the same month elsewhere, for the purpose of filling up blanks when the Tulips die down. Larkspurs transplant very well with care in showery time, or if watered and shaded for a few days.—E. H.

4169.—**Wood Ashes for Lawns.**—If "T. G. W." applies to Mr. P. E. White, 6, Beulah Terrace, Leytonstone Road, London, he can get what wood ashes he may need.

4170.—**Dubbing for Boots.**—1 pint boiled oil (drying oil) 1 pint neat's-foot oil, 1 lb. Russian tallow, ½ lb. beeswax ½ lb. Venice turpentine. Boil for three or four hours in a steam bath, and stir till cold. If it is too thick or stiff add more neat's-foot oil, and boil a few minutes.

4237.—**Roman Hyacinths.**—You can do nothing more after the leaves have decayed than drying off the bulbs and preserving them in bags till next September. It is, however, questionable whether they will repay keeping, as all the best bulbs are imported every autumn.

4214.—**Frozen Cacti.**—It is to be feared that Cactuses that have been frosted so much as to be soft to the touch are injured beyond recovery. The tissue of the plants is naturally soft and succulent, that is, full of water, and the frost would in such wood do considerable mischief. The Cacti are all natives of warm countries, and at all times, even in a state of rest, should be in a temperature not lower than 40°. Keep your plants from the light. Keep moderately dry, and do not push them in any way. If Nature is not crippled she will presently exhibit life.

4217.—**Pruning Clematis.**—Those of your Clematis which bloom early and from the old wood should have that thinned out, and the strongest laid in neatly. Those that make growth from the base of the plant, such as lanuginosa, and bloom late, should have all the wood cut back fairly hard each spring just before the buds start. It is a mistake to allow many shoots to grow. The plants are most effective when the wood is fairly thin and strong.

4227.—**Hyacinths in Glasses.**—The difference is very slight, if any; but it is popularly supposed that blue glass does exert some beneficial influence.—E. H.

4240.—**Floriferous Nasturtiums.**—The scarlet perennial Flame Nasturtiums would no doubt be best for your purpose, but perhaps you mean the annual kinds. Of these the most floriferous, because less coarse, are those obtained from cuttings. However, any good kinds of the Lobbianum section of Nasturtiums, that is, climbing kinds, will do well. Get a packet of seed in mixed colours, and sow the first week in April, protecting from late frosts.

4210.—**India-rubber Plant in Windows.**—The soil must have got sodden and sour for the leaves to become spotted. If so, shake out and repot in rather small pot, using nice, fresh, sandy soil (loam and peat). The culture of this plant is very simple, and if there is sufficient drainage, and not much water given in winter, it can hardly fail.

4211.—**Heating Greenhouse.**—Have nothing to do with gas. Cannot you have your boiler set somewhere away, in back kitchen or yard? Hot water can be carried in 1-in. pipes, 20 or 30 ft. or more with very little loss or trouble.—B. C. R.

4216.—**Leaves of Plants turning Brown.**—The air must be too dry. Keep up a moderate amount of humidity by syringing. Or does any fumes escape into the house from the furnace or flue? A very little of this would do the mischief.—B. C. R.

4220.—**Gloxinias for Winter.**—If the bulbs are starting they should be potted at once and placed in heat. To bloom in winter start them in June or July, and keep them packed in Cocoa-nut fibre, just moist, at a temperature of about 50° till then.—B. C. R.

4159.—**Turnip Beet.**—The Turnip-rooted Beet is a good variety for early use, and indispensable where Beet is required all the year round; it comes into use much before the long-rooted kinds being ready by the beginning of July, during that month, and till September, it is very good, after which it becomes coarse and altogether inferior to the standard varieties.—O. P.

4314.—**Horse-radish in Drain Tiles.**—*C. A. S.*—Three-inch drain tiles will do best. Let them stand out of the ground at least half their length.

4315.—**Frigi Domo.**—*M. E. G.*—

4316.—**Mice and Peas.**—What is the best way to prevent rats and mice eating sown Peas where they cannot be destroyed?—L. B. M. [Well rub the Peas in red lead before sowing, or soak them in paraffin oil. Also cover the rows with coal ashes. Chopped Gorse or Furze put in the row over the Peas is a preventive.]

4317.—*Arthur.*—We know of no book specially devoted to the subject. Hassard's "Floral Decorations" might suit you. It can be had from the publisher at our office.

4318.—*H. A. P.*—We know of no Scarlet Runner with a red leaf. Cut the Geraniums down and place them in a window, keeping them rather dry. The monthly parts of GARDENING appear early in each month.

4319.—**Plants from Seed.**—When must I put in seeds of Verbenas, Pyrethrums and Campanulas to flower the same year? Are Castor-oil plants difficult to raise from seed?—BROWN EYES. [Sow at once in a greenhouse or warm window. Castor-oil plants are easily raised from seed sown in a warm, moist atmosphere.]

4320.—*Oncidiums.*—Write to the publishers of the book or enquire at some bookstall.

4321.—**Chestnuts in Water.**—*W. C. H.*—Treat these and the Potatoes exactly like you do the Acorns,

4322.—**Hot water Pipes under Gateway.** I have two greenhouses, one of which is heated by hot-water pipes, and should like to continue pipes into the other, but a gateway intervenes. Will it answer if I carry the pipes down under the gateway and up the other side into the other house.—F. W. W. [Yes; provided the lowest pipe under the gateway is higher than the top of the boiler.]

QUERIES.

Notice.—*In consequence of the great increase in this department it may often be necessary to insert answers to queries of unusual length in other parts of the paper. Querists, therefore, who do not find their answers in the usual department will find them in the body of the paper.*

4323.—**Hepaticas.**—How many species and distinct varieties of this hardy perennial are to be met with in garden cultivation? and is there a double white?—ENQUIRER.

4324.—**Apple Trees in Bleak Aspect.**—Three years ago I planted an avenue of Apples in my orchard, intending to grow them as standards. They broke well; they were then two years old. As the shoots grew I began from the bottom gradually to cut them off; they were then 6 or 7 ft. high. Since that time scores of large timber trees have been cut down that sheltered them, and this is now become one of the bleakest spots I know of anywhere. It is useless to think of growing them as standards; the mighty winds blow everything down. Now my bearing wood is gone, at least the lower part of the trees, there is plenty at the top, as their heads have not been cut off. To try and meet the case in May last year, instead of cutting back, I bent them down, to induce them to break, but they broke very little. How should I treat them now? Can I train them over arches with any prospect of success? if so, how should I proceed?—J. E., *Dunstable.*

4325.—**Grubs on Currant Trees.**—Against the north wall of my garden are nailed Currant trees (White, Red, and Black), and for several summers past the entire leaves have been eaten up by a small grub or caterpillar, which unfolds itself in the centre of the leaf. I shall be glad if any reader will inform me of a remedy.—SUBSCRIBER.

4326.—**Deal Staining.**—Will some reader give a receipt for staining plain deal mahogany or oak colour?—A. C.

4327.—**Heating a Fern Case.**—I have a small Fern case with a few Maiden-hair and other half-hardy ferns in it, which I would like heated in a cheap, effectual way. I propose burning a small, smokeless paraffin lamp. Would this prove effectual, and not be injurious to the plants? The room I keep it in is rather cold, a fire being in it but seldom.—C. F. C. S.

4328.—**Roses on Bowers.**—Against a wall of my garden, facing the north, I have a summer-house placed where the border from wall to walk is about 8 ft. wide. In front of the summer-house, and over the entrance thereto and running out to the walk, I have had erected an arch-shaped bower made of laths, the length of which is 6 ft. Over the bower from each side I would like to plant and train Roses. How many should I plant? and which are the best sorts for the purpose, taking into account the situation? also the best mode of preparing the soil for planting and the best time to plant, adding any additional hint which would guide to a successful issue.—SCOTCH THISTLE.

4329.—**Stocks for Plum Trees.**—Will any reader inform me if the common wild Sloe forms a good stock for a Plum tree? and if slips grown from Plum seeds would be proper grafts for the same?—LESLIE.

4330.—**Climbers for Church Walls.**—What creepers should be planted against the east and west walls of a brick church near London? Of course they must take care of themselves, as the church is lofty.—F. L. S.

4331.—**Deutzias with Small Blooms.**—Can anyone tell me why my Deutzias are now opening miserably little greenish blossoms instead of the full, pure white clusters they generally bear? They are young plants struck from cuttings last year, and planted out in the open ground for the summer. In the autumn they were potted and left out-of-doors till they had lost their leaves, since which time they have been in an ordinary greenhouse temperature.—AVE.

4332.—**Mercury or Goose-foot.**—Is the Chenopodium Bonus Henricus, or Mercury or Goose-foot, ever cultivated for eating, as a substitute for Spinach, anywhere except in Lincolnshire? I have never seen it since I left Lincolnshire, where every garden, large or small, has a bed of Mercury.—C. B

4333.—**Lilium lancifolium.**—Would S. D. Sanders, who gave an interesting account of his Lilies in No. 96, January 8, kindly state what compost he used? and what situation they were placed in? also if he thought the same could be grown to any perfection in the north of Scotland, where frosts continue till late in the spring and commence early in autumn? I should be thankful if he would give some hints as to their treatment there.—ABERNETHY.

4334.—**Plants for Small Beds.**—What plants would be most suitable for two rather large half-circle beds, one in a sunny aspect, the other more shelter ed? Last year it took eight dozen bedding plants to fill them. I have Geraniums, Calceolarias (brown and yellow), and Fuschias, saved through the winter, and I can raise seeds, as we have a hotbed.—BROWN EYES.

4335.—**Ferns for Greenhouses.**—Having a small greenhouse, which I purpose keeping at night during the winter months at a temperature of 45°, I should feel obliged for a list of Ferns which would succeed in it, to include as many varieties as possible of Adiantums (Maid n-hair); also soil and treatment. I can get plenty of fibrous peat from the mountains in the neighbourhood.—A BEGINNER.

4336.—**Tacsonias Frosted.**—What is the best treatment for a crimson Tacsonia which was caught by the last severe frost. Must it be cut down? or will it spring out again? It has been planted three years and has not flowered yet.—BROWN EYES.

4337.—**Plants for Borders.**—What plants are most suitable for a border 3 ft. wide, with an east aspect, but sheltered by a wall 7 ft. high; length of border 40 yds.? There is an edging of Box.—BROWN EYES.

4338.—**Stocks and Asters in Pots for Exhibition.**—Can any reader give me information how to grow Stocks and Asters in pots? what size pots and soil would suit them best? and when should the seed be sown to be ready for exhibition in the middle of August?—COTTAGER.

4339.—**Tropæolum speciosum.**—I wish "Q Q." in his interesting and encouraging letter as to growing Tropæolum speciosum had said what part of England was alluded to. I have seen it growing beautifully in Sussex, but that is near the sea, as are all places in which I have heard of its flourishing.—W.

4340.—**Propagating Clematis.**—Will some one tell me the best time for striking cuttings of Clematis Jackmani without a greenhouse? the length of the cutting to be taken? and the soil best adapted to ensure success? I have tried a great many, but have always failed.—CLEMATIS JACKMANI.

4341.—**Sparrows in Gardens.**—What can I do to get rid of the sparrows which literally destroy all the young crops in my garden?—H. H.

4342.—**Kalosanthes.**—Will someone give me full directions as to the proper treatment all the year round of Kalosanthes? I have twelve young plants in a large pan, which are now between 7 in. and 8 in. high, some with two shoots.—ENGLISH WALES.

4343.—**Passion-flowers in Towns.**—Will Passion-flowers do well in towns?—CITY OF LIVERPOOL.

4344.—**Raspberries in the Shade.**—Will some reader tell me if I could grow Raspberries successfully on a plot of ground, 7 ft. south of which a row of old Beech trees are growing?—SILVER STORK.

4345.—**Cherries for Orchards.**—Will anyone inform me which sort of Cherry is best adapted for orchard culture as a standard? A dark variety preferred, and must be a hardy and prolific bearer.—PAX.

4346.—**Lilies for Mixed Borders.**—Wanted, the names of six Lilies best suited for a mixed border. They will not be more than 4 ft. from the edge of the walk, and will be planted in line with Rose bushes, tall Phloxes, &c. I want to leave them where planted, and the situation is just on the outskirts of a town.—A. W. S., *Hull.*

4347.—**Uncovering Roses.**—During winter all my Rose trees have been covered at the roots with a good lot of litter. When should I remove this? Last year the trees began to shoot under the litter before the frost went away, and the long weak shoots were soon nipped when the litter was taken away from them.—A. W. S., *Hull.*

4348.—**Vegetables on Clayey Bank.**—Against the end wall of my garden, and having a south-eastern aspect, is a clay bank, some 24 ft. by 6 ft. I have dug it deeply several times during the past year and freely mixed coal ashes with it, but it is still very stiff. What vegetable crop would succeed best on it? Would a couple of rows of Jerusalem Artichokes do well? or would it be better for common herbs, such as Mint, Fennel, &c.?—NONDESCRIPT.

4349.—**Solanums for Next Year.**—I have a few Solanums in a sitting-room window, the berries of which are beginning to shrivel and the leaves to turn rather brown. I wish to have them in fruit next autumn. What treatment should they receive to obtain the desired result?—NUT.

4350.—**Mignonette.**—Last April I sowed some Mignonette in the open ground, and it grew long shoots, but it was not strong enough to stand up of itself, so it crept on the ground. The shoots would be 2 ft. 6 in. long; the flowers were very few and small and without any perfume, but there was an abundance of small bell-shaped pods. What can I do in future to keep it more dwarf, and have it larger, with the sweetly-perfumed flowers?—NUT.

4351.—**Laurustinus Injured by Cold.**—I have three Laurustinuses outside my sitting-room window, which lately got buried in the snow. The side shoots appear to have been partially killed by the cold and snow. What can I do to save them, and have them nice plants again by the autumn of this year?—NUT.

4352.—**Improving Vegetable Land.**—My garden, the soil of which is rather light and gravelly, with sand 2 ft. 6 in. below the surface, has been frequently manured. Will a good dressing of chalk be of any advantage to it? or would a moderate dressing of gas lime once a year be preferable? Also, what Plum trees would be most likely to succeed in the same soil on a wall with south aspect? Garden exposed to sea breezes and strong S.W. winds.—CONSTANT READER.

4353.—**Espalier Training.**—About three years ago I cut down the leading shoots of half-a-dozen young Pear trees, intending to form them into espaliers, but I now find I did not cut the shoots low enough, there being at present 1 ft. or more of bare stem between the ground and first side branches. Would the young trunks be likely to break fresh shoots if cut down to within 6 in. of the ground, although there are no appearance of eyes in the bark? They present an extremely gawky appearance as they are.—YOUNGSTER.

4354.—**Salt and Lime for Potatoes.**—A very successful grower of Potatoes uses the following proportions: Twenty bushels of lime and ten bushels of salt to the acre, and says "when the ground is in fairly good heart he believes it more beneficial to the growth of Potatoes than animal or vegetable manure." Where in London can I get the kind of salt required?—T. W.

4355.—**Lapagerias.**—I have an opening between my house and that of my neighbour's, 4 ft. wide by 12 ft. long, which I have roofed in with glass; aspect south, but the house only gets the sun three or four hours a day; general collection of plants do not thrive satisfactorily, but Ferns do very well. Will a Lapageria be likely to succeed trained under the glass roof? and should I plant it outside, or keep it in a pot inside?, and will it afford sufficient shade for my Ferns? If the Lapageria is not suitable, what climber will do? I only just keep out the frost.—CONSTANT SUBSCRIBER.

4356.—**Soil for Fuchsias, &c.**—What is the very best compost for Fuchsias and Geraniums? Is fibrous peat of use for them?—A BEGINNER.

4357.—**Tulip Tree not Flowering.**—I have a Tulip tree which was planted 20 years ago, and is a fine healthy tree. It has never shown any signs of flowering. What is the cause?—M. E. G.

4358.—**Camellias during their Flowering Season.**—What treatment do Camellias require whilst flowering?—J. L.

4359.—**Planting Pansies.**—I have about six dozen Pansy cuttings (choice sorts) which were potted in 4-in. pots in October. How ought I to proceed now so as to get a good show of flowers? and when should they be put into beds?—NOVICE.

4360.—**Liquorice.**—I have half an acre of rich deep sandy loam, and would like to try to grow Liquorice. I understand it is grown from crowns or offshoots. Where can I get any to plant? and what price per cwt. will it realise when ready to dig?—A FARMER.

4361.—**Roses for Small Pots.**—What are the best Roses to grow in small pots? What is the best soil, treatment, &c., for them?—A BEGINNER.

POULTRY.

Poultry Breeding for Profit.—"A Constant Subscriber," who wishes a cross to produce size, quality, and hardiness, must use his judgment to combine these qualities from pure breeds. For size on table, Dorkings, Houdans, and Asiatics. For quality, Game. For hardiness, Brahmas and Houdans. I know of no breed which will give a plentiful supply of large eggs all the year round, but Houdans lay very large eggs, and Spanish and Hamburgh lay the greatest quantity, but the eggs are small. I consider Brahma, or Cochin, and Houdan a very useful all round cross, and Brahma Dorking is an old favourite sort. If spring chickens for market or exhibition are required you should have hatched one incubator full of, say, 90 or 250 eggs last month, and another should have been hatched the first week in February. If you only require ordinary poultry for your own table or country markets no time for even that should be lost. It is always considered best to make up breeding pens by 1st of January.—I. D.

Poultry Produce.—We (*Rugby Advertiser*) have been presented by Mr. George Loverock with a few unusually fine eggs, which it may interest our readers to know are the produce of cross-bred fowls, *i.e*, Brahma and Dorking. Some of these eggs weigh from 3½ oz. to 4 oz. and possess two yolks. This gentleman has also a Toulouse goose that began to lay Jan. 5, and has laid every other day an egg weighing 7 oz. We are very pleased to notice successful efforts of poultry fanciers, holding strong opinions of the great benefits derivable from poultry farming as a source of wealth and comfort to many who now sigh in vain for the delicacies that might be placed within their reach.

Eggs with thin Shells.—Can any reader inform me the reason why our fowls lay eggs with thin shells? They have a large open yard, with large piece of grass for a run, and access to plenty of mortar and lime. They are fed upon plenty of grain and soft food in the shape of cooked vegetables, &c.—SUBSCRIBER.

Fowls for Clayey Soil.—What is the best breed of fowls to keep on damp, heavy clay soil? I have a large grass run and dry houses. I have not found Dorkings answer well.—ESSEX PARSON.

Scales on Fowls' Legs.—This is generally caused by fowls being allowed to run about in damp, dirty weather, or, if confined, caused by dirty runs. When fowls go to roost they pick or straighten their feathers after a wet day, and the scales, or the pith that comes from the root of the feathers, as well as from the body, sticks to their damp legs. The roost of fowls should at all times be kept particularly clean. To cure those affected bind a piece of rag round the leg well moistened with common salad oil. Change it every other day for a fortnight. Do not pull the scales off, or your fowls will have sore legs. Let it come off itself. Cover a clean rag over the oiled rag, so that the oil will not interfere with the plumage of the birds. It is not infectious.—J. H., *Petworth.*

Brahma Fowls in Small Spaces.—"Leho" will find one cock and seven hens quite sufficient for so small a space, especially if any of the eggs are required for hatching. Sawdust is not a good thing in hen-houses; the fowls eat it, and it is very indigestible; ashes and lime are the best.—I. D.

Eggs without Yolks.—Will some one kindly tell me the reason why one of my fowls lays small eggs lately without any yolks? Last year she laid large perfect eggs.—W. Y.

Fowls with Swollen Heads.—Can any one tell me a remedy for a disease in poultry which seems to commence by the eyes being watery, and the nostrils swellings; then the side of the face swells tremendously; at first possibly one side as large as a small walnut and quite hard? We have had fowls which have first had inflamed faces, then a swelling set in as hard as a bullet and quite white. I put on a drawing ointment, the sort of bullet cracked and peeled off as perfectly white as the surroundings of the eyes of a boiled cod-fish; in many cases the fowls have entirely lost their eyes. We have now three turkeys affected with this disease, and I shall be thoroughly obliged to any one who will tell me what to do with them. We have had the poultry houses stoned, disinfected, &c. All this time the fowls are healthy, the turkeys have had the disease for weeks, but they still eat their food.—A WEEKLY SUBSCRIBER.

KITCHEN BOILER EXPLOSIONS.

THE usual list of killed and wounded from this cause has already far exceeded its average annual proportions. Why such a cumbrous and costly mode of heating baths is persisted in is difficult to tell, but it is probable that until the plumber is made liable to be brought up for manslaughter there will be no change. The average Briton is far too conservative to give up an old system for a better. There is not the slightest reason why a kitchen or bath boiler should ever explode if properly fixed by a plumber who has the smallest amount of common sense. There are two simple ways by which an explosion can be totally prevented—one by fixing a dead weight safety valve which should be for convenience fixed when the apparatus is put up first. The other is to cut a hole in the hot water return pipe a little distance above the boiler, this hole being from ½ in. to 1 in. in diameter, and to solder over this a piece of sheet lead about 1-32 in. thick, just sufficient to safely stand the general water pressure, making, in fact, a weak place in the system of pipes which will be the first to give way. This hole must be cut in such a position that the pipe is certain to be warmed from the fire, and as near as possible to the boiler. It must also be where, in case of the sheet lead being blown out the water will not be thrown into the room, but into the fire, so as to extinguish it. Any plumber should do this for a shilling or two, and although it is liable to make a mess it only does this when an explosion would occur in its absence. It is also easy to put an escape pipe through which the water could be led away to the outside of the building in case of accident. This thin lead safety disc might be made so as to fix in a brass socket and be easily replaced if an accident did occur. The whole system of circulating boilers as at present fixed is radically wrong, as, with few exceptions, the hot water is rarely to be got when wanted in any quantity, and the cost in fuel expended is utterly out of proportion to the useful result obtained. There are many simpler, cheaper, and more satisfactory arrangements which can be fixed at less than one-tenth the cost, and of all these the best is a galvanised iron or copper cylinder of about eight gallons capacity, with a tap, and a good gas-heating burner underneath it, the cylinder having a loose lid and a water-supply tap over it for filling as required. After some months' daily experience with this there is no doubt that it is far cheaper to use than the circulating boiler system, and far more useful for general work. It has also the advantage of absolute safety under any possible condition. In case of a stoppage preventing the use of the kitchen fire, the use of gas for cooking prevents the slightest difficulty or inconvenience. This has now attained such perfection that it is more than probable that a good gas cooking apparatus, even if got as a makeshift, will quickly find its proper place, and permanently supersede the fire for all work. It is generally considered that circulating boilers with a reserve cylinder are safe from explosion. This is a mistake, as a case where the cylinder burst and flooded a house has come under my notice within the last few days, and this is by no means the first accident of the kind which I have known.

Warrington. THOS. FLETCHER, F.C.S.

Use of Spent Tan.—A few weeks ago a question was asked and answered as to the utility of old or spent tan. Tan thoroughly decomposed, of course, becomes vegetable soil, and makes an excellent top-dressing for borders or beds of flowers where the soil happens to be stiff or clayey, giving such beds a warm, neat appearance; but the best use to which I have seen it applied was as a mulching for Strawberries, about 4 in. of the material being spread between the rows, as the rains will wash down the particles, leaving 1 in. or more of the coarser material on the top, which instantly becomes dry, on which the fruit when ripe will lie as on a slate. I have seen fresh tan applied extensively to Thorn hedges when newly planted; about 6 in. thick was laid on each side of the Thorns. This acted as a cooling medium in dry summers after planting, and, owing to the tan being raw and fresh, not a weed would come through it; the year after the tan was dug in among the soil, and no doubt helped to feed the young trees.—T. W. O.
